

# Inelastic X-Ray Scattering

These slide are for  
distribution to the Cheiron  
Summer School Students.

Alfred Q.R. Baron  
Materials Dynamics Laboratory (RIKEN)  
Research and Utilization Division (JASRI)  
SPring-8

# Scope & Outline

Huge & Complex Topic - Appropriate for a semester, not an hour...

## Main Goal:

Introduce Capabilities & Put them in Context

What properties can be measured?

Why consider these techniques?

## Outline:

Introduction

Instrumentation

Non-Resonant

Resonant

Others (time permitting)

# Scientific Information

(from IXS)

**Atomic Dynamics <-> Motions of atoms in a solid (phonons) or liquid.**

Phase transitions, thermal properties, fundamental science (Atomic binding)

Electron-phonon coupling, Magneto-elastic coupling

Superconductors, Ferroelectrics, multiferroics, etc

**Electronic Dynamics <-> Motions/transitions of electrons**

Chemical Bonding (Valence, etc)

Electronic Energy Levels (atomic/molecular)

Delocalized Electronic Excitations

Generalized Dielectric Response

Fermi-Surface Topology

Magnetic structure

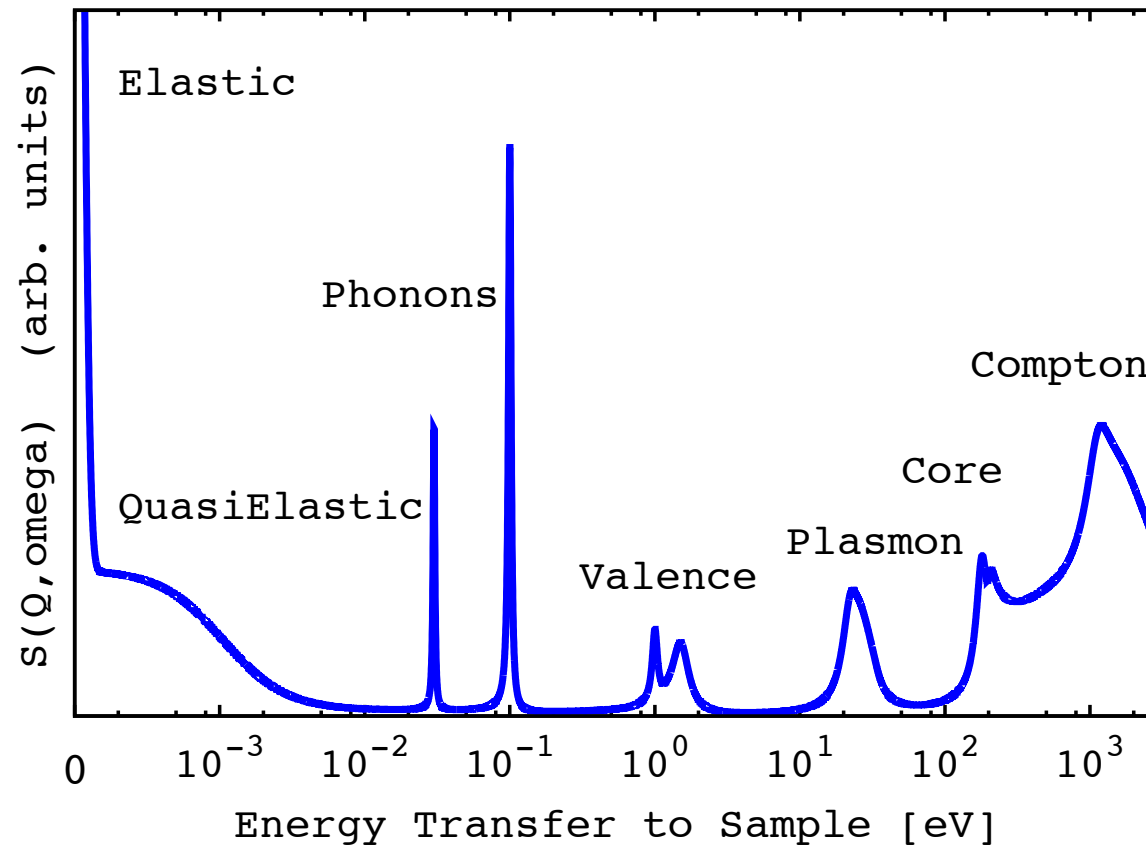

Complex Materials

# Table Of IXS Techniques/Applications

Technique	Comment	Energy Scale	Information
X-Ray Raman	(E)XAFS in Special Cases	$E_{in} \sim 10 \text{ keV}$ $\Delta E \sim 100-1000 \text{ eV}$	Edge Structure, Bonding
Compton	Oldest Note: Resolution Limited	$E_{in} \sim 150 \text{ keV}$ $\Delta E \sim \text{keV}$	Electron Momentum Density Fermi Surface Shape
Magnetic Compton	Weak But Possible	$E_{in} \sim 150 \text{ keV}$ $\Delta E \sim \text{keV}$	Density of Unpaired Spins
RIXS Resonant IXS	High Rate Somewhat Complicated	$E_{in} \sim 4-15 \text{ keV}$ $\Delta E \sim 1-50 \text{ eV}$	Electronic Structure
SIXS Soft (Resonant) IXS	Under Development Now Exploding	$0.1-1.5 \text{ keV}$ $\Delta E \sim 0.05 - 5 \text{ eV}$	Electronic & Magnetic Structure
NRIXS Non-Resonant IXS	Low Rate Simpler	$E_{in} \sim 10 \text{ keV}$ $\Delta E \sim <1-50 \text{ eV}$	Electronic Structure
IXS High-Resolution IXS	Large Instrument	$E_{in} \sim 16-26 \text{ keV}$ $\Delta E \sim 1-100 \text{ meV}$	Phonon Dispersion

Note:  $\Delta E$  = Typical Energy Transfer (Not Resolution)  
Note also: Limit to FAST dynamics ( $\sim 10 \text{ ps}$  or faster)

# Excitation Energy Scales

# Spectroscopy

## Absorption vs. Scattering

### Absorption Spectroscopy

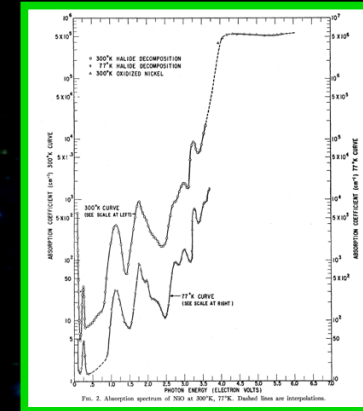

Optical, IR, NMR

Raman

Measure absorption as you scan the incident energy

When energy hits a resonance, or exceeds a gap, or... get a change

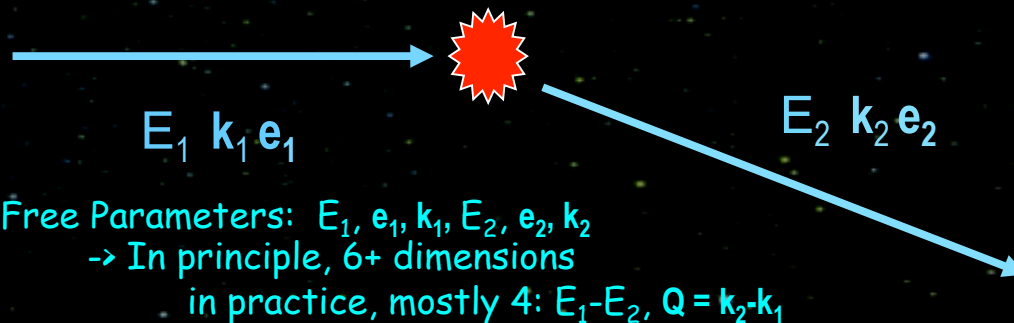

Free Parameters:  $E_1, e_1, k_1$   
 -> In principle, 3+ dimensions  
 but in practice mostly 1 ( $E_1$ )

Optical Spect. NiO  
 Newman, PR 1959

### Scattering Spectroscopy

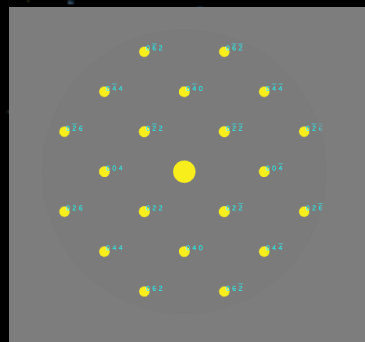

IXS, INS

Scattering is more complex, but gives more information.  
 Energy scales PLUS spatial structure on scale of probe wavelength

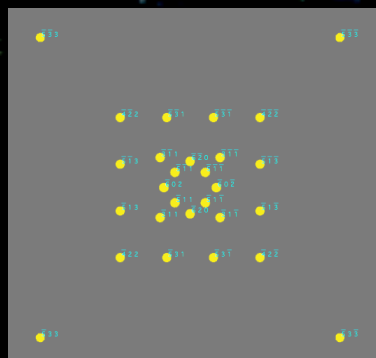

# Where We Are Measuring Between the Bragg Peaks...

Conventional Diffraction  
Linear Scale

Precession Photo

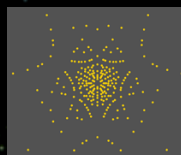

Silicon

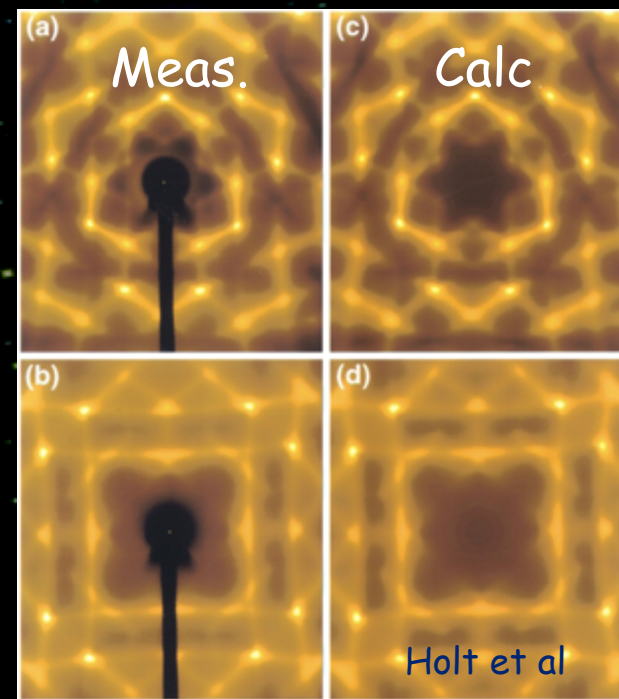

Laue Photo

Bragg peaks

Ruby

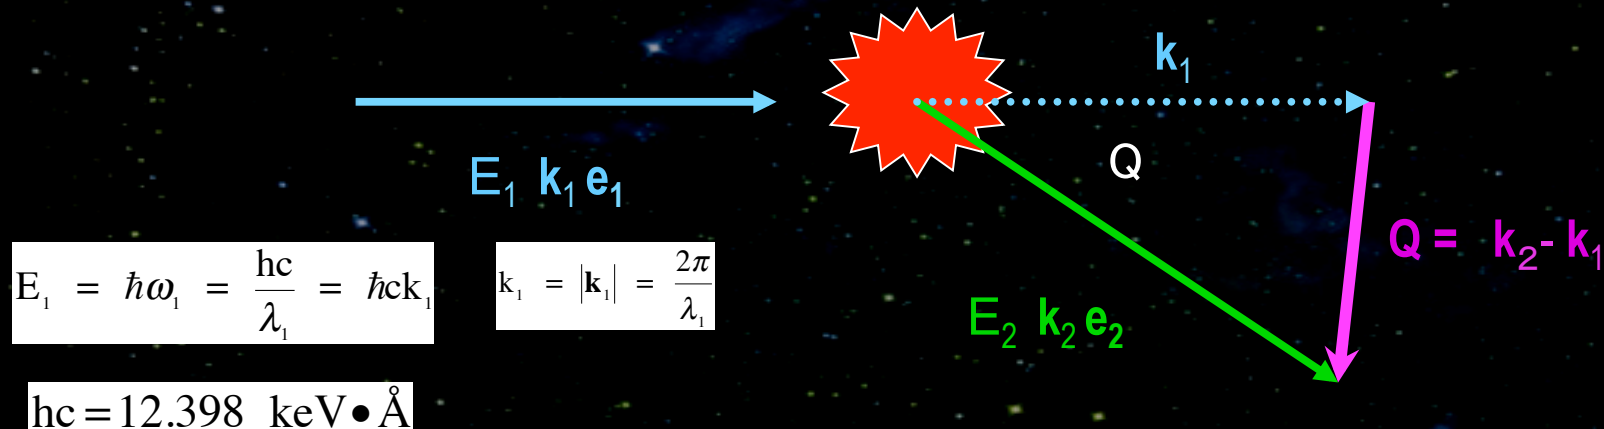

On Log Scale

For IXS we are usually measuring between the Bragg peaks where the intensity is weaker. A strong signal is down by  $10^7$ , weak by  $10^{11}$

# X-Ray Scattering Diagram

## Two Main Quantities:

### Energy Transfer

$$E \text{ or } \Delta E = E_1 - E_2 \equiv \hbar\omega$$

Note: For Resonant Scattering  
 $E_1$  and  $E_2$  and Poln.  
 Are also important

### Momentum Transfer

$$\mathbf{Q} \equiv \mathbf{k}_2 - \mathbf{k}_1$$

$$Q \equiv |\mathbf{Q}| \approx \frac{4\pi}{\lambda_1} \sin\left(\frac{\Theta}{2}\right)$$

Periodicity  $d = \frac{2\pi}{|\mathbf{Q}|}$

# Resonant vs Non-Resonant

Resonant:

RIXS  
SIXS

Tune near an atomic transition energy  
ie: K, L or M Edge of an atom

Generally High Rate

Complex interpretation

Energy fixed by resonance -> poorer resolution

Non-  
Resonant:

IXS  
NRIXS

Far from any atomic transition.

Small cross-section

Interpretation directly in terms of electron density

Choose energy to match optics -> good Resolution

Different Experimental Setups -> Modern Specialization

Nuclear Resonant & Compton Scattering -> Different

# Dynamic Structure Factor

It is convenient, especially for non-resonant scattering, to separate the properties of the material and the properties of the interaction of the photon with the material (electron)

$$I_{\text{scattered}}(\mathbf{Q}, \omega) \propto \frac{d^2 \sigma}{d\Omega d\omega} = r_e^2 \left( e_2^* \cdot e_1 \right)^2 \frac{\omega_2}{\omega_1} S(\mathbf{Q}, \omega)$$

$$\sigma_{\text{Thomson}} = r_e^2 \left( e_2^* \cdot e_1 \right)^2$$

Thomson Scattering  
Cross Section  
“A Scale Factor”

$$S(\mathbf{Q}, \omega)$$

Dynamic Structure Factor  
“The Science”

# Different Views of $S(\mathbf{Q}, \omega)$

$$S(\mathbf{Q}, \omega) = \sum_{\lambda, \lambda'} p_{\lambda} \left| \langle \lambda' | \sum_{\text{electrons } j} e^{i\mathbf{Q} \cdot \mathbf{r}_j} | \lambda \rangle \right|^2 \delta(E_{\lambda'} - E_{\lambda} - \hbar\omega)$$

Transition between states

Fluctuations in electron density

$$= \frac{1}{2\pi\hbar} \int dt \, d^3r \, d^3r' \, e^{-i\mathbf{Q} \cdot \mathbf{r}} \langle \rho(\mathbf{r}', t=0) \rho^+(\mathbf{r} + \mathbf{r}', t) \rangle \rightarrow N \sum_{\mathbf{q}} \sum_{\text{Modes}} \left| \sum_{\substack{d \\ \text{Atoms} \\ \text{Cell}}} \frac{f_d(\mathbf{Q})}{\sqrt{2M_d}} e^{-W_d(\mathbf{Q})} \mathbf{Q} \cdot \mathbf{e}_{\mathbf{q}d} e^{i\mathbf{Q} \cdot \mathbf{x}_d} \right|^2 \delta_{(\mathbf{Q}-\mathbf{q}), \tau} F_{\mathbf{q}}(\omega)$$

$$= \frac{1}{\pi} \frac{1}{1 - e^{-\hbar\omega/k_B T}} \text{Im}\{-\chi(\mathbf{Q}, \omega)\} = \frac{1}{\pi} \frac{1}{1 - e^{-\hbar\omega/k_B T}} \frac{1}{v(\mathbf{Q})} \text{Im}\{-\epsilon^{-1}(\mathbf{Q}, \omega)\}$$

Generalized Response  
(e.g. Dielectric functions)

See Squires, Lovesy, Shulke, Sinha (JPCM 13 (2001) 7511)

# Why is it Better to Measure in Momentum/Energy Space?

For diffraction (and diffractive/coherent imaging), one goes to great lengths to convert from momentum space to real space. If possible, a direct real-space measurement would (sometimes) be preferred.

Equilibrium Dynamics:  $Q, E$  space is what you want.

Normal modes  $\rightarrow$  peaks in energy space  $\rightarrow$  clear and "easy"

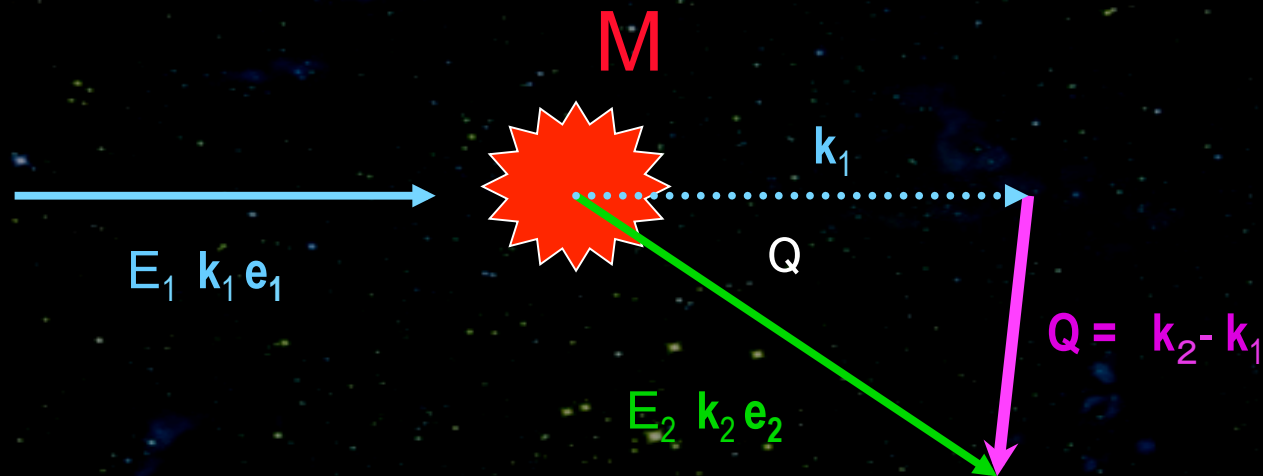

Periodicity of crystals  $\rightarrow$  Excitations are plane waves  
 $\rightarrow Q$  is well defined

Non-equilibrium dynamics  $\rightarrow$  Real space  $(x, t)$  can be better.

Non-periodic (disordered) materials  $\rightarrow$  Expand in plane waves. (oh well)

# Kinematics

Conservation of Energy

Kinetic Energy Given to Sample:

$$E_{\text{recoil}} = \frac{p^2}{2M} = \frac{\hbar^2 \mathbf{Q}^2}{2M}$$

Take:  $M=57 \text{ amu}$ ,  $Q/c = 7 \text{ \AA}^{-1} \rightarrow E_r=2.3 \text{ meV}$

f-sum rule:

$$\frac{\int d\omega \hbar\omega S(\mathbf{Q},\omega)}{\int d\omega S(\mathbf{Q},\omega)} = \frac{\hbar^2 \mathbf{Q}^2}{2M}$$

Compton Form:  $\lambda_2 - \lambda_1 = \frac{h}{Mc} (1 - \cos \Theta)$

$$\lambda_c = \frac{h}{m_e c} = 0.0243 \text{ \AA}$$

# The IXS Spectrometer

## *An Optics Problem*

### Main Components

#### Monochromator:

Modestly Difficult

Accepts  $15 \times 40 \mu\text{rad}^2$

#### Sample Stages

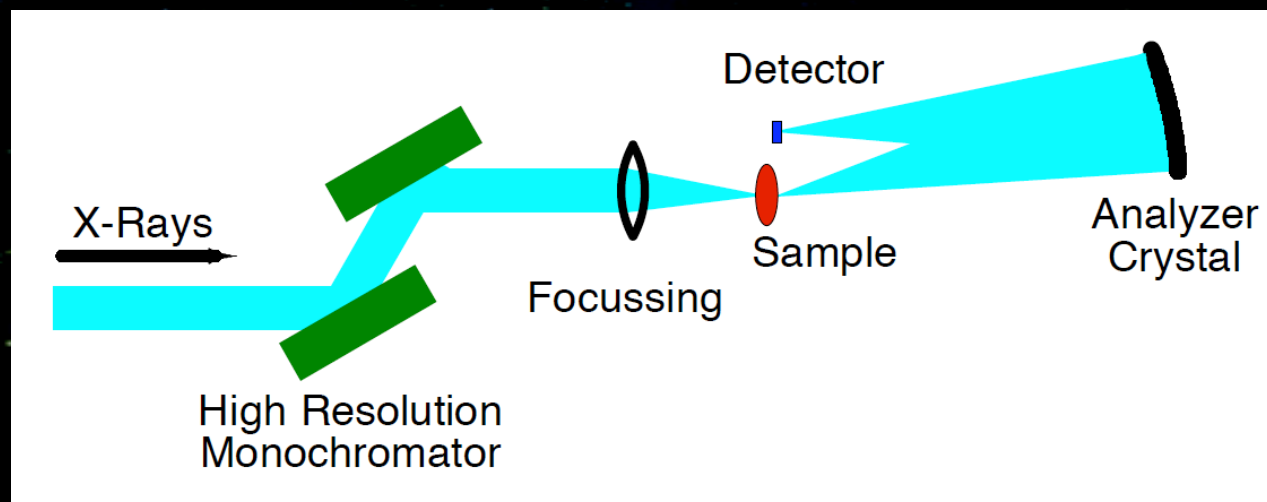

Straightforward

Only Need Space

#### Analyzer:

Large Solid Angle

Difficult

The Goal: Put it all together and  
Keep Good Resolution, Not Lose Flux

Note: small bandwidth means starting flux reduced by 2 to 3 orders of magnitude...

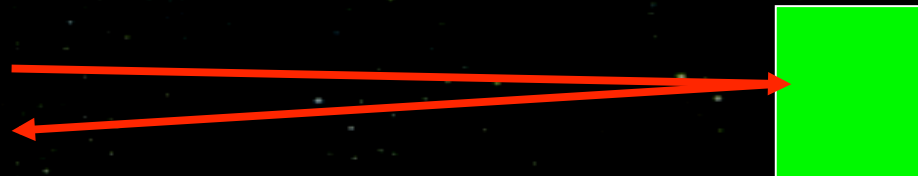

# Basic Optical Concept

(Hard x-rays)

Bragg's Law :  $\lambda = 2d \sin(\Theta_B) \Rightarrow \Delta\theta = \tan(\Theta_B) \frac{\Delta E}{E}$

Working closer to  $\Theta_B \sim 90$  deg. maximizes the angular acceptance for a given energy resolution...

Better energy resolution  
-> Closer to 90 degrees  
-> Large Spectrometer

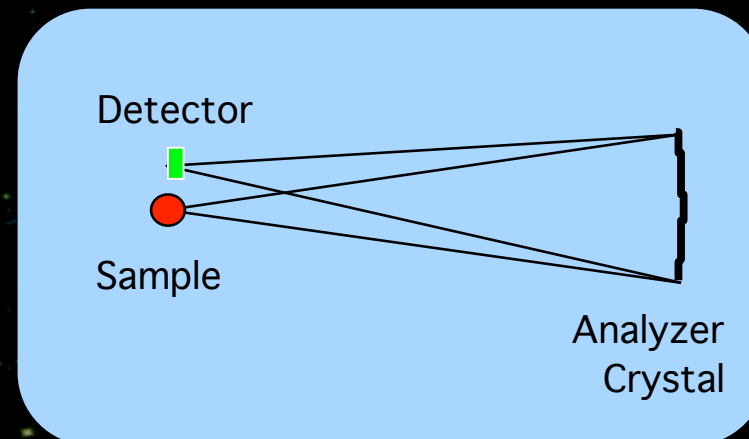

# High Resolution Analyzer Crystals

The more difficult optic...

## Require:

Correct Shape (Spherically Curved,  $R=9.8$  m)

Not Strained ( $\Delta E/E \sim \text{few } 10^{-8} \rightarrow \Delta d/d < \text{few } 10^{-8}$ )

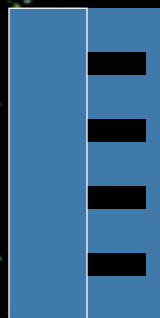

Method: Bond many small crystallites to a curved substrate.

1. Cut

2. Etch

3. Bond to Substrate

4. Remove Back

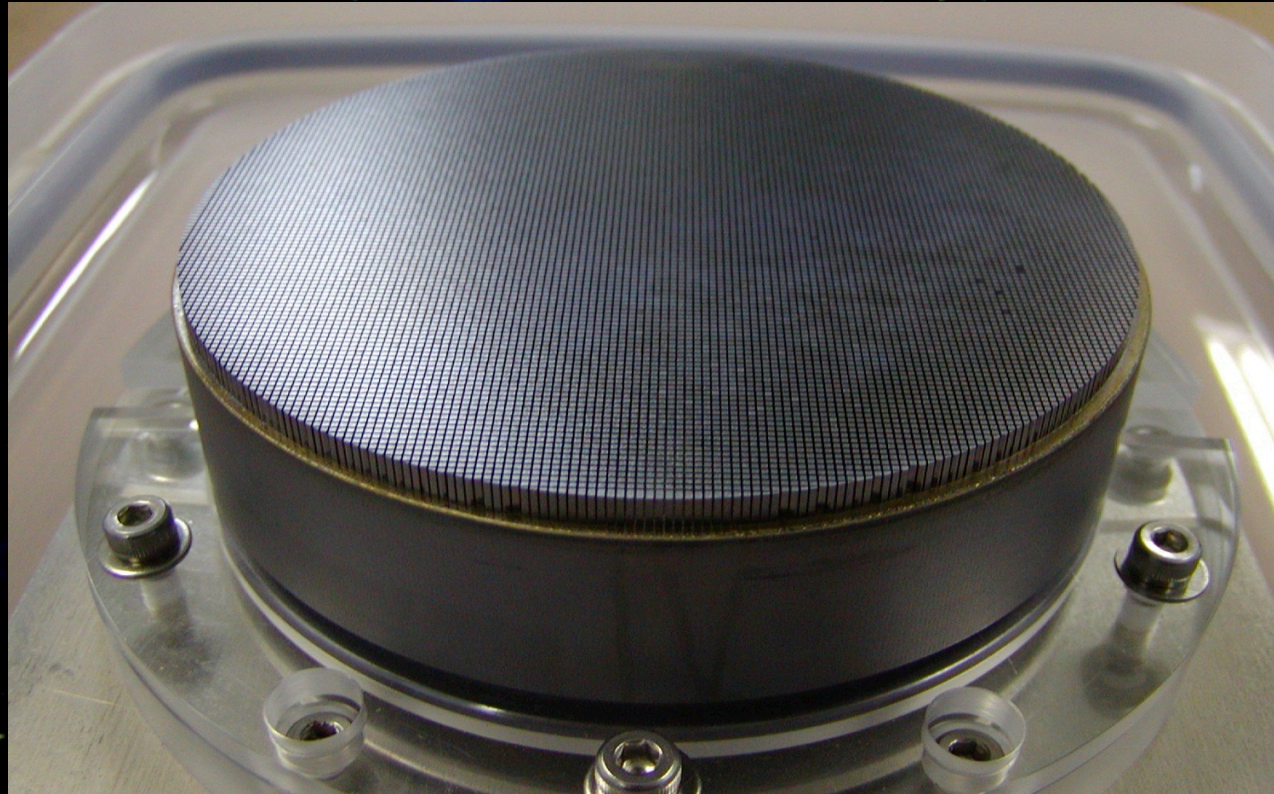

X-Rays

$10^4$  Independent Perfect Crystals

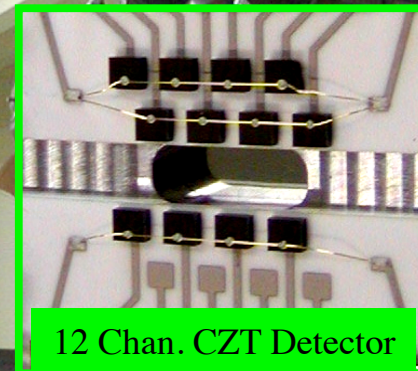

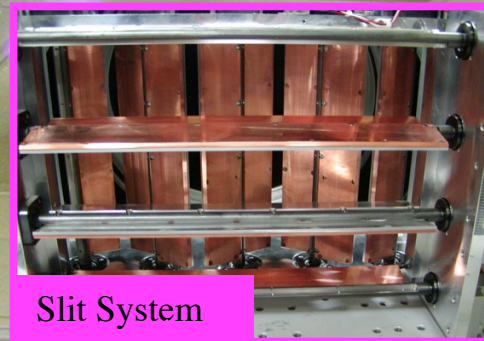

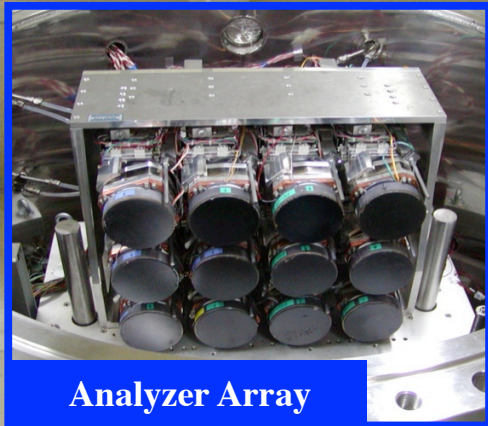

Note: For resolution  $>300$  meV, bending can be OK.

# Analyzer Crystal

*9.8 m Radius, 10cm Diameter*  
50 or 60  $\mu\text{m}$  blade, 2.9 mm depth, 0.74 mm pitch  
Channel width (after etch):  $\sim 0.15$  mm  
60 to 65% Active Area

# A High (meV) Resolution Spectrometer

Sample

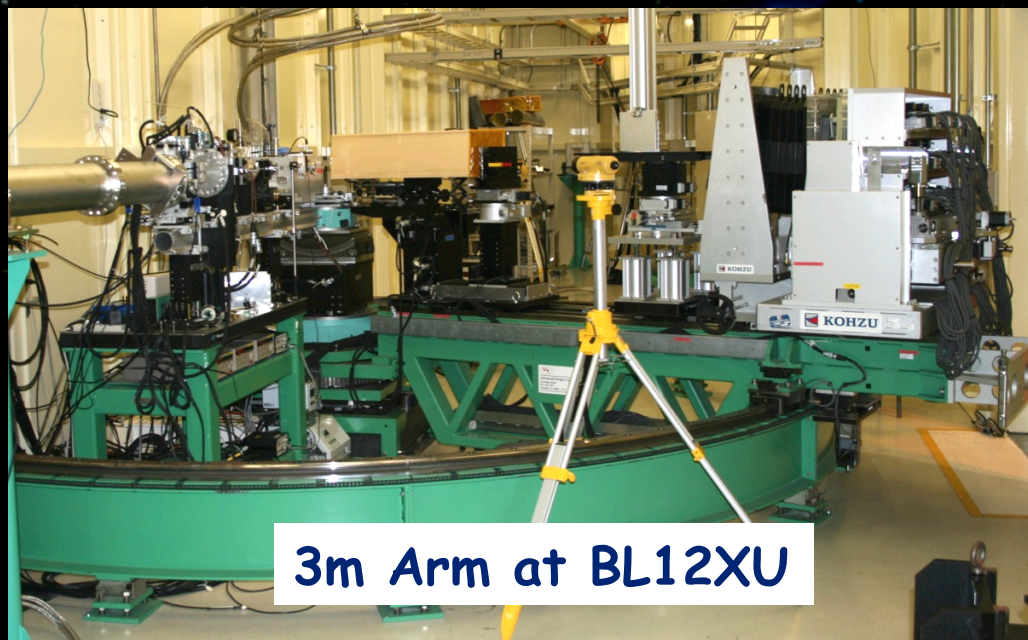

Vacuum Flight Path

Incident Beam  
 $\phi \sim 100 \mu\text{m}$   
 $\phi 20 \mu\text{m}$  Possible

10m Horizontal Arm - to  $55^\circ$  in  $2\theta$

Granite Base w/Airpads

# A Medium Resolution Spectrometer

3m Arm at BL12XU

Medium Resolution Spectrometer:  
 Arm Radius: 1 to 3 m  
 Resolution:  $\sim 0.1$  to 1 eV  
 Used for RIXS and NRIXS

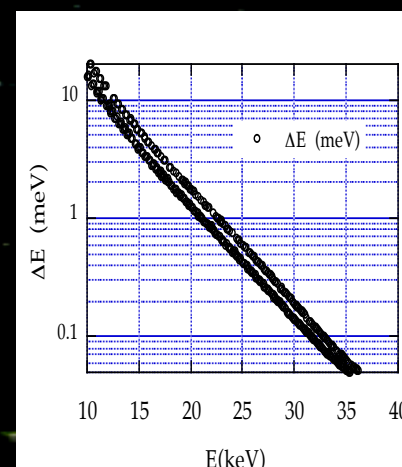

BL12XU    BL11XU    BL43LXU

Shorter Possible  
 (later, if time)

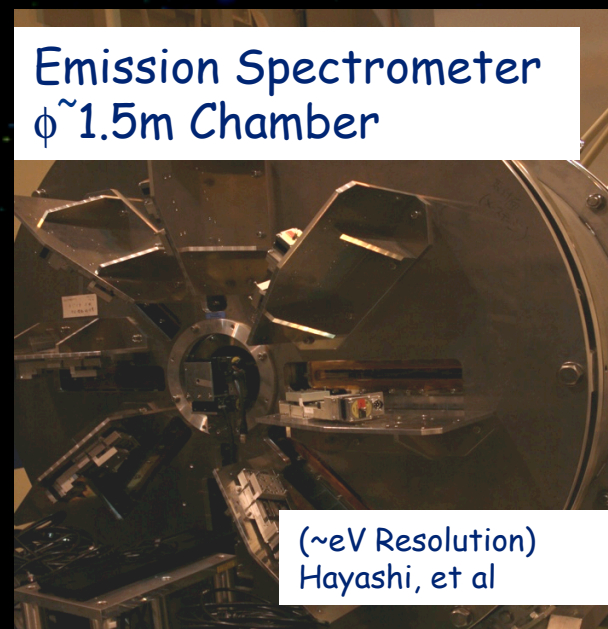

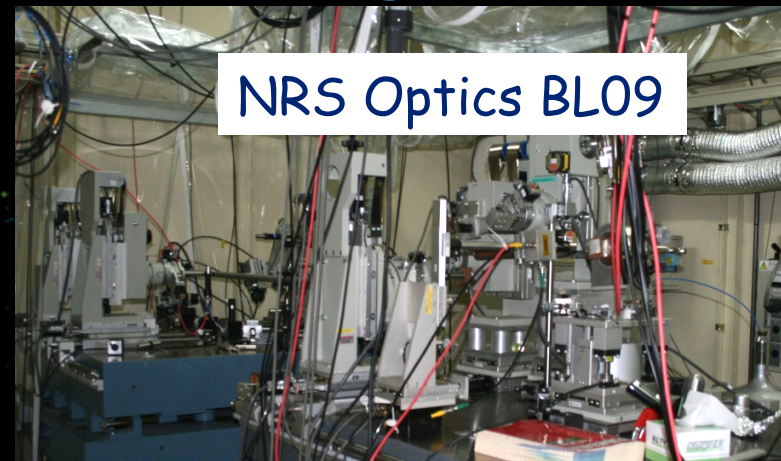

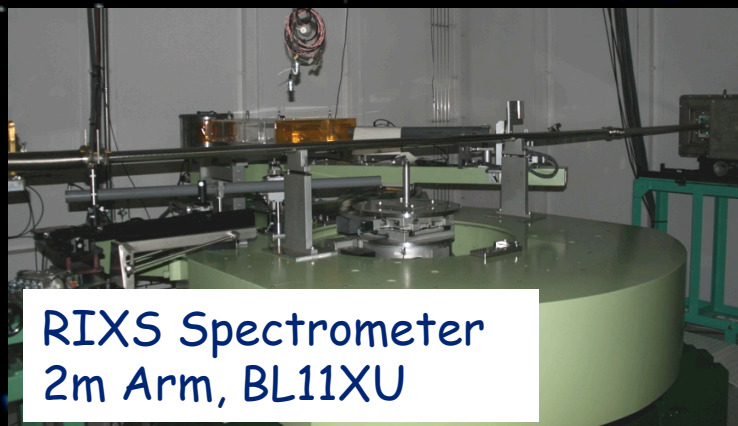

Note difference between RIXS and NRIXS

NRIXS: Choose the energy to match the optics

RIXS: Resonance chooses energy  $\rightarrow$  usually worse resolution

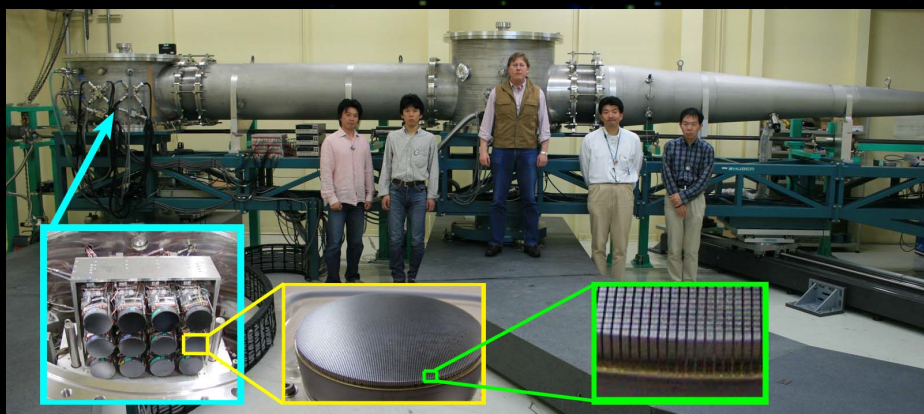

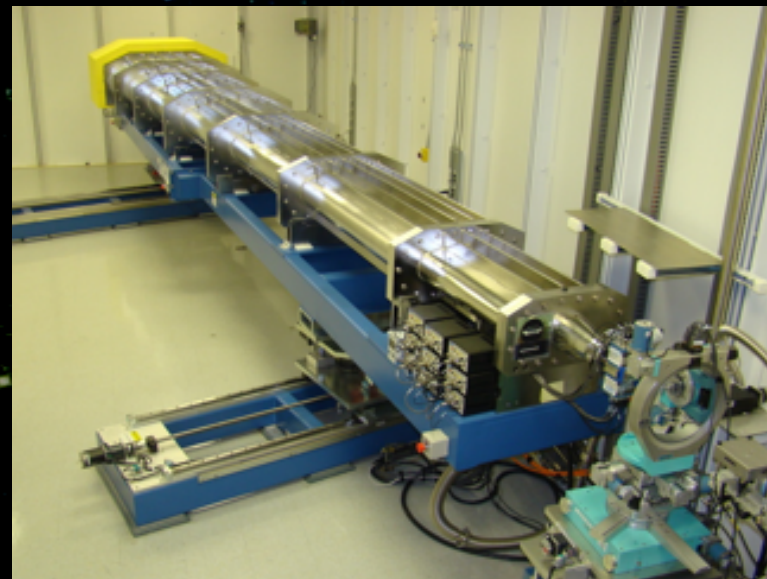

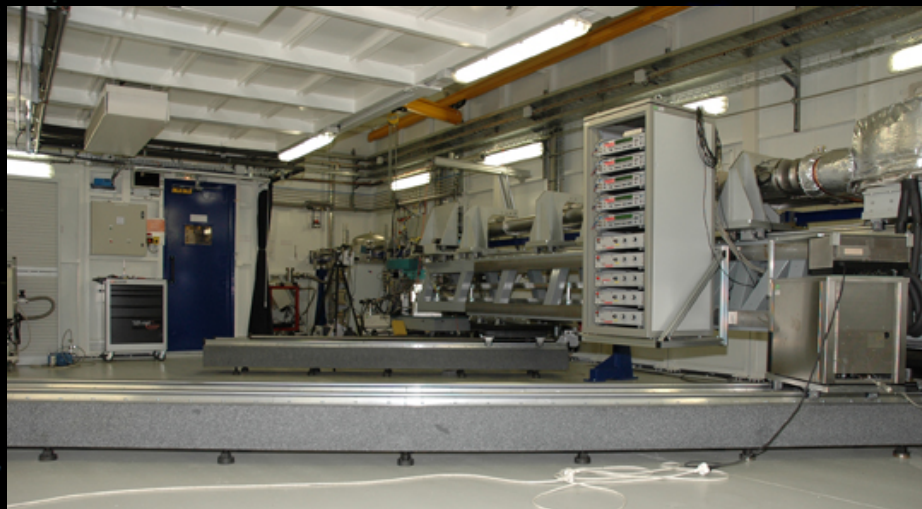

# Other Spectrometers @ SPring-8

# High Resolution Spectrometers

ESRF (ID28)

APS (Sector 30)

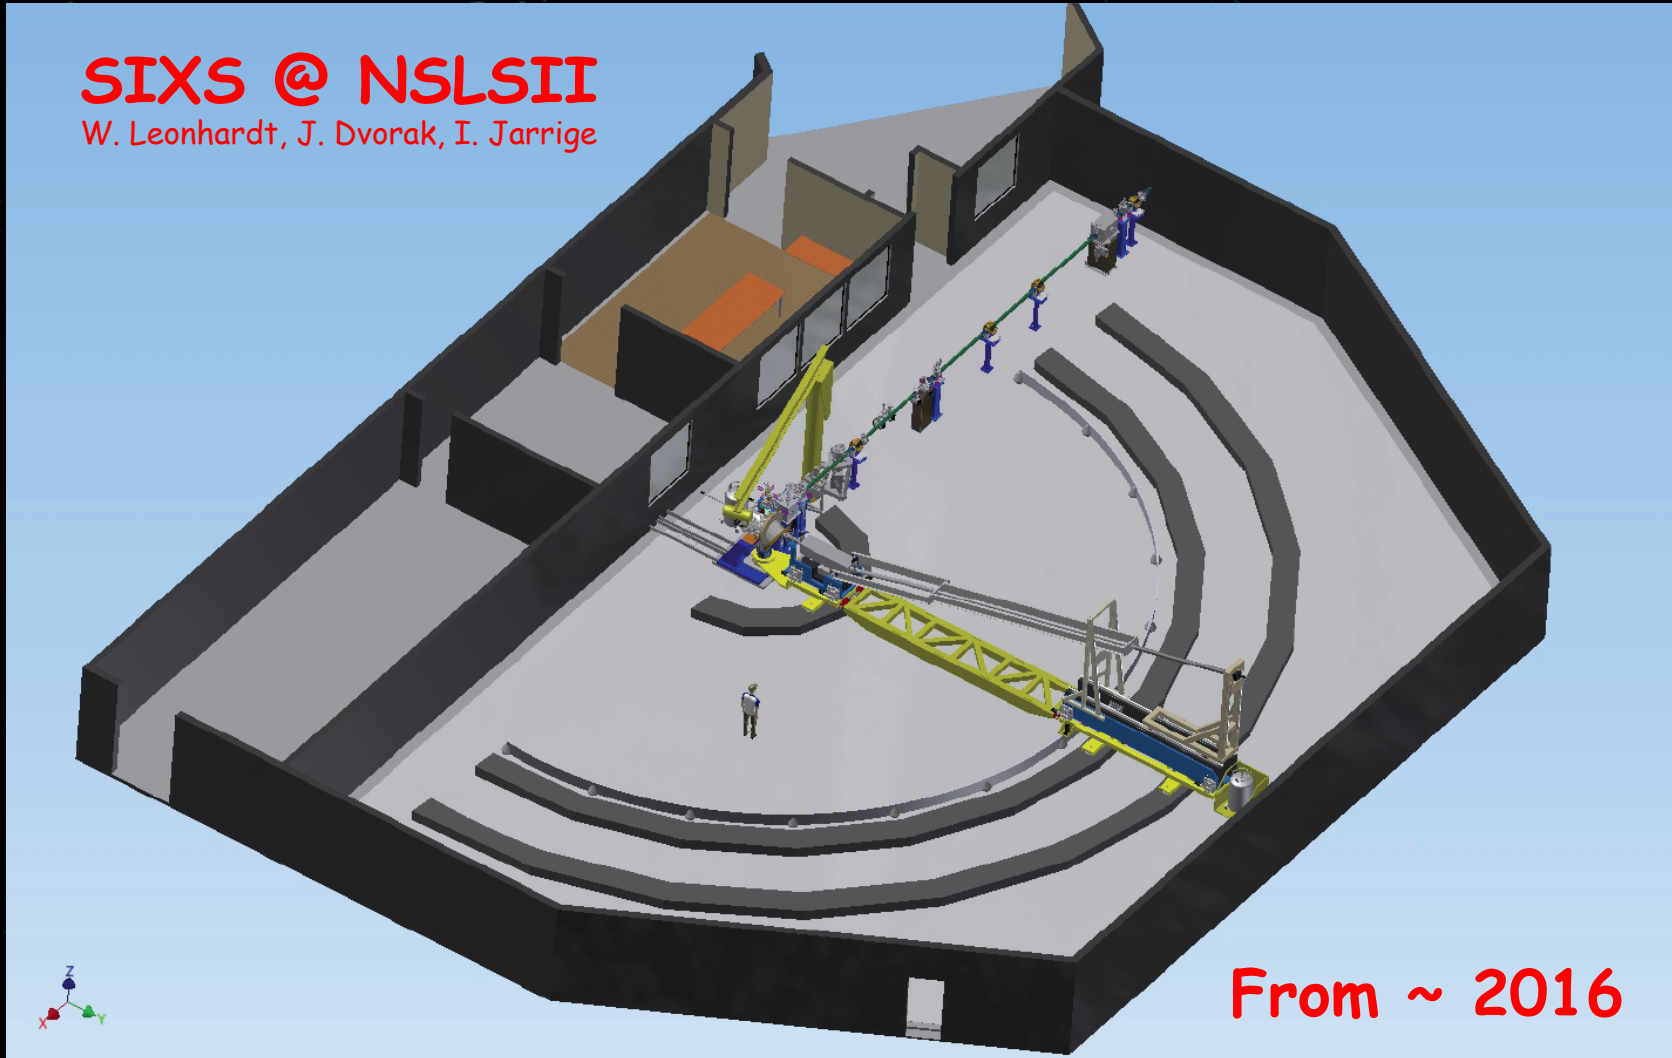

HRIXS  
~10m scale instruments

SPring-8 BL35XU

# Softer and Bigger...

## SIXS @ NSLSII

W. Leonhardt, J. Dvorak, I. Jarrige

From ~ 2016

Soft inelastic x-ray scattering: 10 meV resolution at 1 keV via gratings

# Atomic Dynamics: Systems and Questions

## Disordered Materials (Liquids & Glasses):

Still a new field -> Nearly all new data is interesting.

How do dynamical modes survive the cross-over from the long-wavelength continuum/hydrodynamic regime to atomic length scales?

## Crystalline Materials:

Basic phonon model does very well -> Specific questions needed.

Phonon softening & Phase transitions (e.g. CDW Transition)

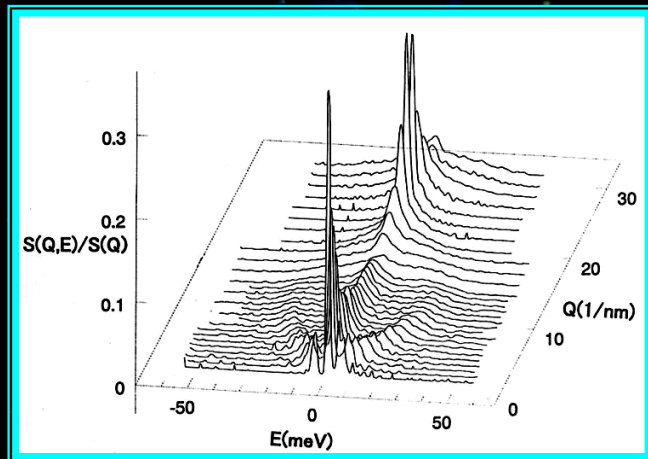

Thermal Properties: Thermoelectricity & Clathrates  
Sound Velocity in Geological Conditions

Pairing mechanism in superconductors

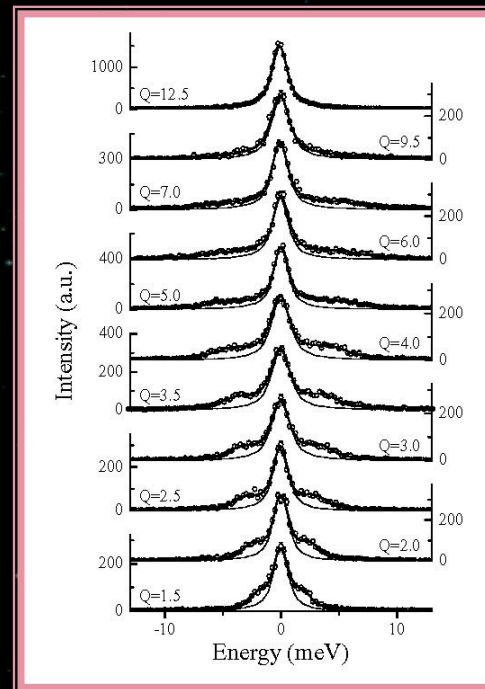

# Disordered Materials

Liquids & Glasses

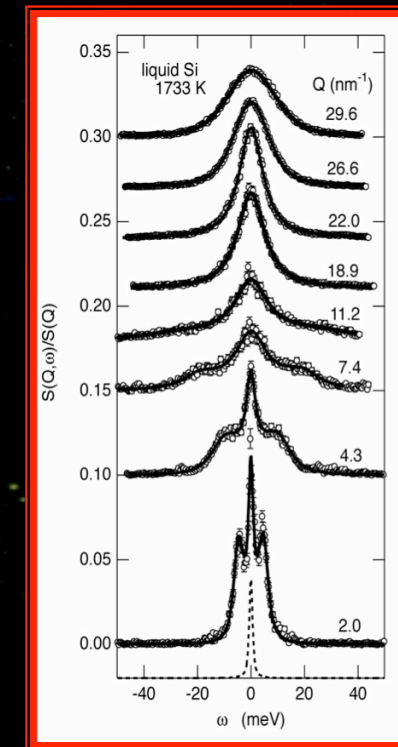

First Glance: Triplet response similar for most materials.  
Dispersing Longitudinal Sound Mode  
+ Quasi-Elastic peak

**l-Mg** (Kawakita et al)

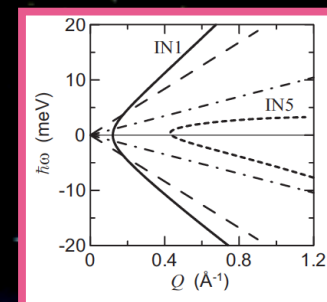

**α-Se** (Scopigno et al)

**l-Si** (Hosokawa, et al)

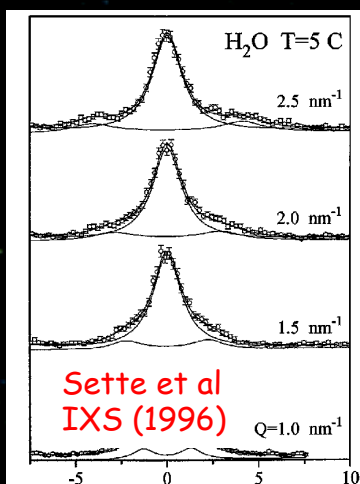

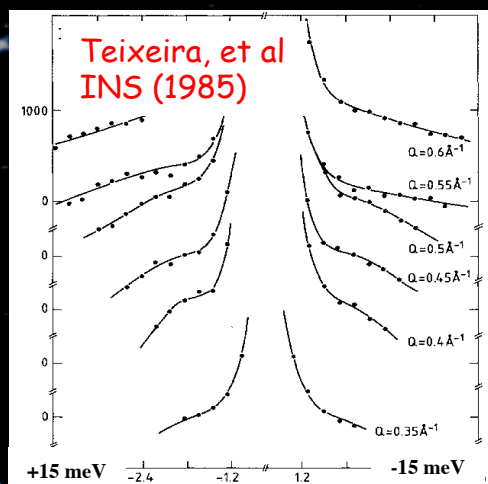

# The IXS Advantage

IXS has no kinematic limitations ( $\Delta E \ll E_\gamma$ )  
 Large energy transfer at small momentum transfer  
 -> excellent access to mesoscopic length scales

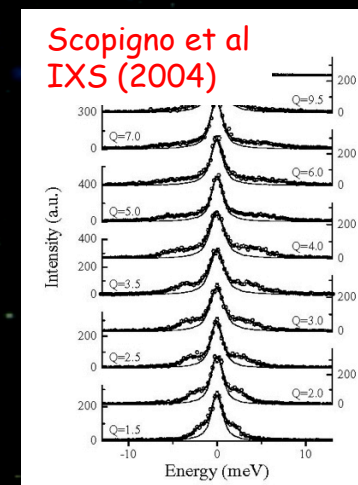

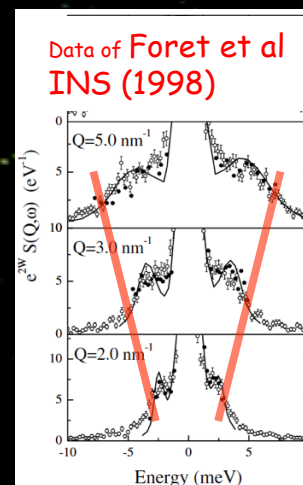

INS  
Diagram

## Water

## Glassy-Se

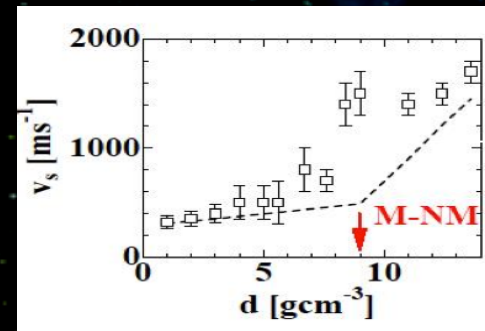

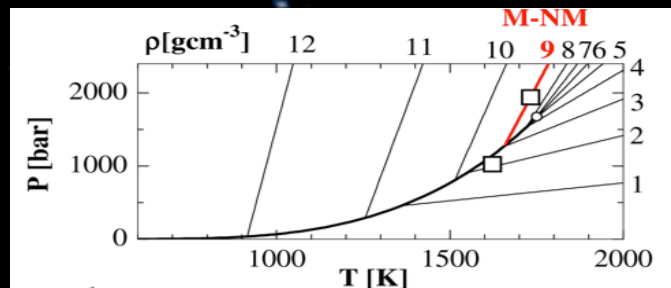

Also: No Incoherent Background  
 Small Beam Size ( $\phi < 0.1\text{mm}$ )

But:  $< 1\text{ meV}$  resolution is hard  
 Low Rates for Heavy Materials

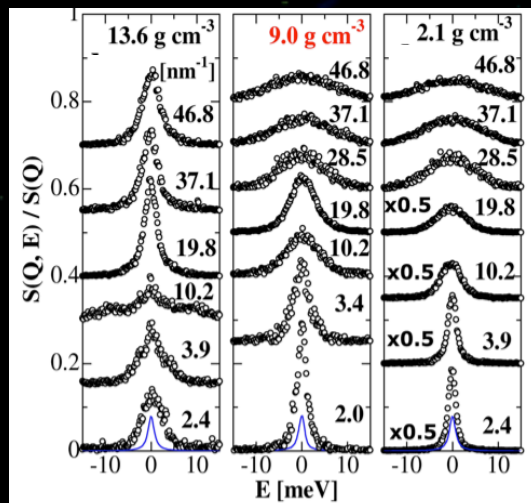

# "Fast Sound" at the Metal-Non-Metal Transition in Liquid Hg

Universal Phenomenon in Liquids:

Expand a liquid metal enough and it becomes an insulator.

Ultrasonic Velocity

Suggests a change in the microscopic density fluctuations...

Probably general phenomenon...  
but no confirmation yet.

(Next M-I transition under discussion)

Ishikawa, Inui, *et al*, PRL 93 (2004) 97801

~2 months of beam time...

# On Positive Dispersion

Very General feature:

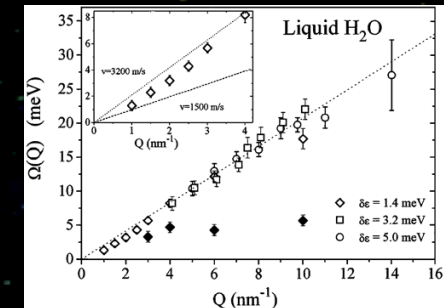

As  $Q$  increases the phase velocity of the acoustic mode becomes larger than the Low- $Q$  (e.g. ultrasonic) sound velocity.

Casual explanation

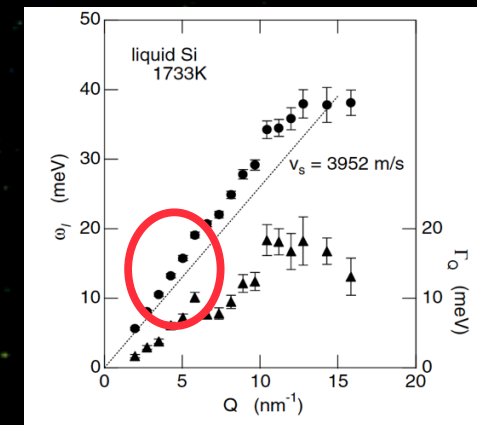

For smaller length scales (high  $Q$ ) and higher frequencies, a liquid, locally, resembles a solid which has a faster sound velocity.

Partial explanation in terms of a visco-elastic model...

Scopigno & Ruocco RMP 2005  
Ruocco & Sette CMP 2008  
Bryk et al JCP 2010

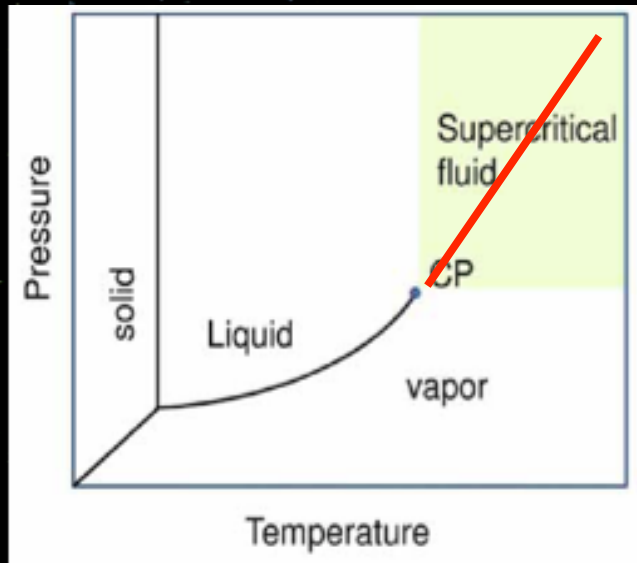

Sette et al

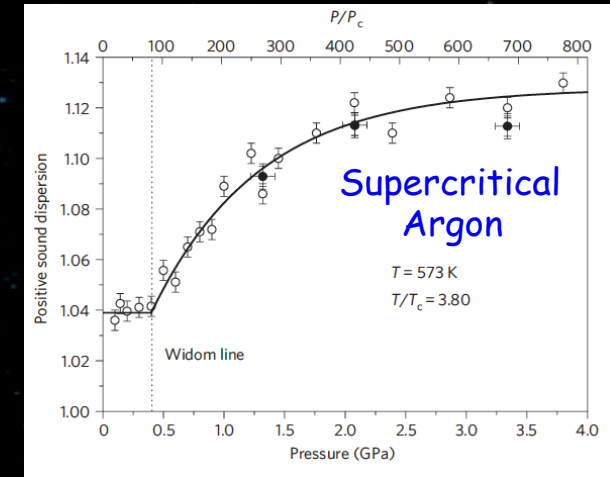

Hosokawa, et al

# Dynamical Distinction

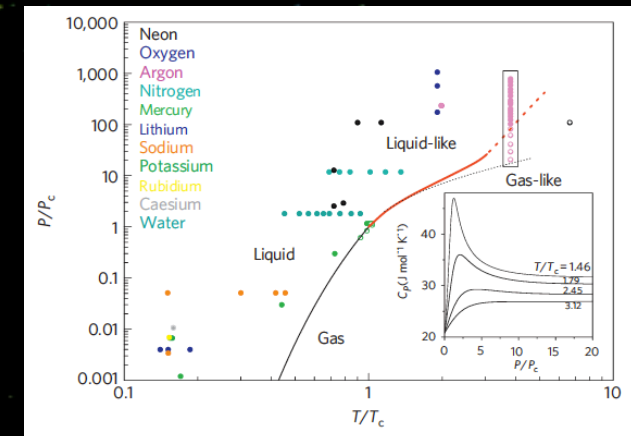

Widom Line  
Maximum in  $C_p$

Simeoni et al NPhys 2010

Take the presence of Positive Dispersion  
as the definition of liquid-like behavior

Gorelli et al, PRL (2006)  
Simeoni et al, NPhys (2010)  
Also Bencivenga et al EPL (2006)

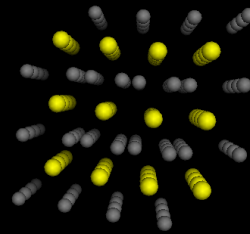

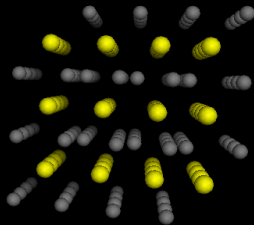

AQRB @ AOFSSR Cheiron School 2013

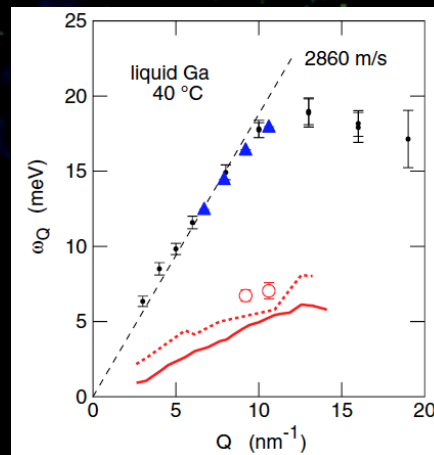

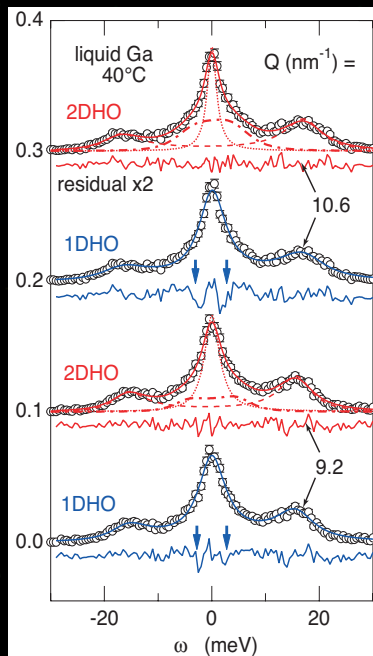

# Shear Mode in a Simple Liquid

Pressure Wave in a Liquid:  
Nearly Always Visible

Shear Wave -> Harder...

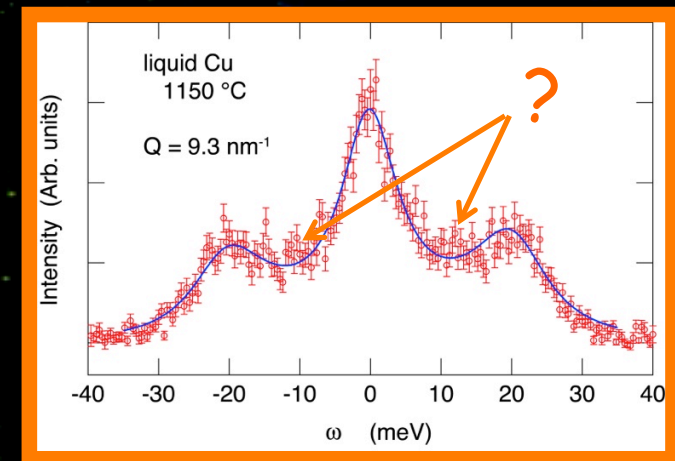

$$S(\mathbf{Q}, \omega) \approx \int dt e^{-i\omega t} \int d\mathbf{r} \int d\mathbf{r}' e^{i\mathbf{Q} \cdot (\mathbf{r} - \mathbf{r}')} \langle \rho(\mathbf{r}', t) \rho(\mathbf{r}, t = 0) \rangle$$

Weak, but significant, signal.

Hosokawa, et al, PRL (2009)

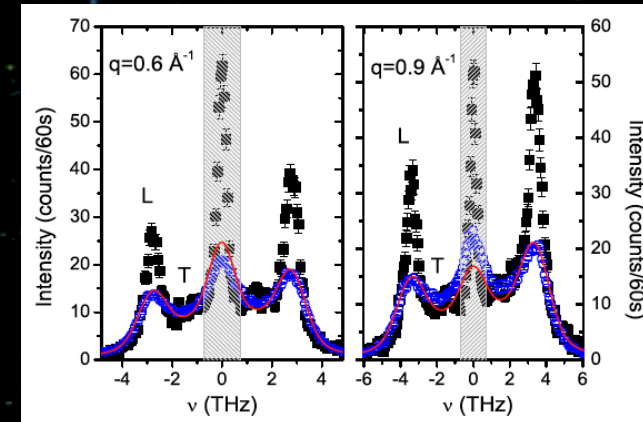

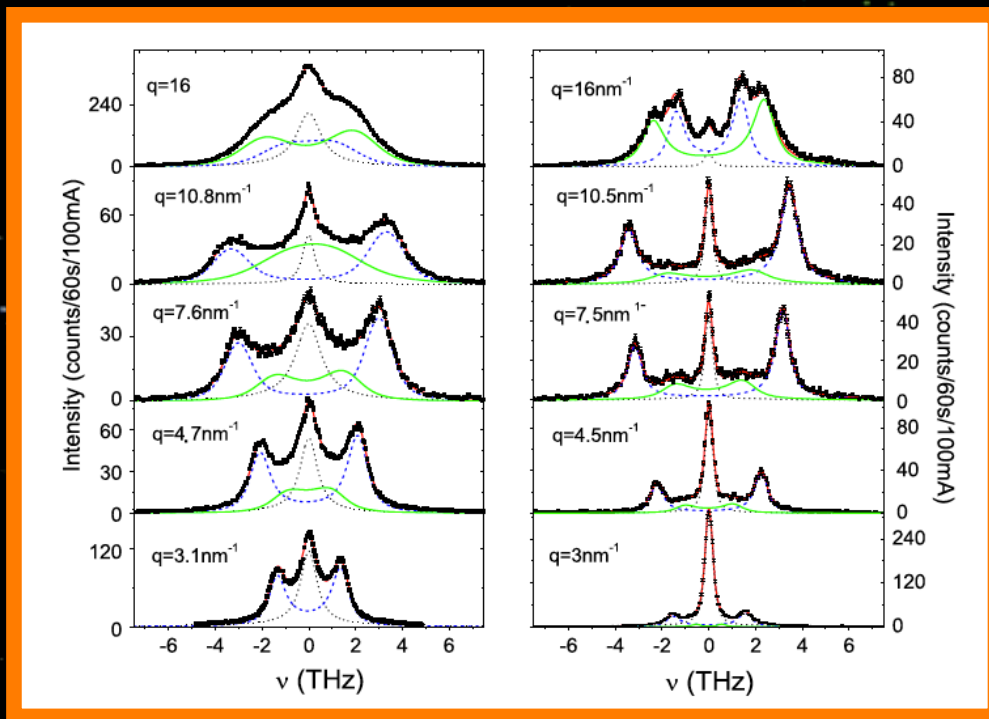

Next experiment: l-Cu  
2.5 Days -> ?

# Liquid Excitations = Solid + Disorder?

Giordano & Monaco, PNAS (2010)

IXS from Na: Above & Below  $T_M$

Black = Polycrystalline Na  
Blue = Liquid Na

Red = Polycrystal + Scaling by  
Density, T, & Blurring...

Not bad ...

# Phonons in a Crystal

Normal Modes of Atomic Motion = Basis set for small displacements

Must have enough modes so that each atom in a crystal can be moved in either x,y or z directions by a suitable superposition of modes.

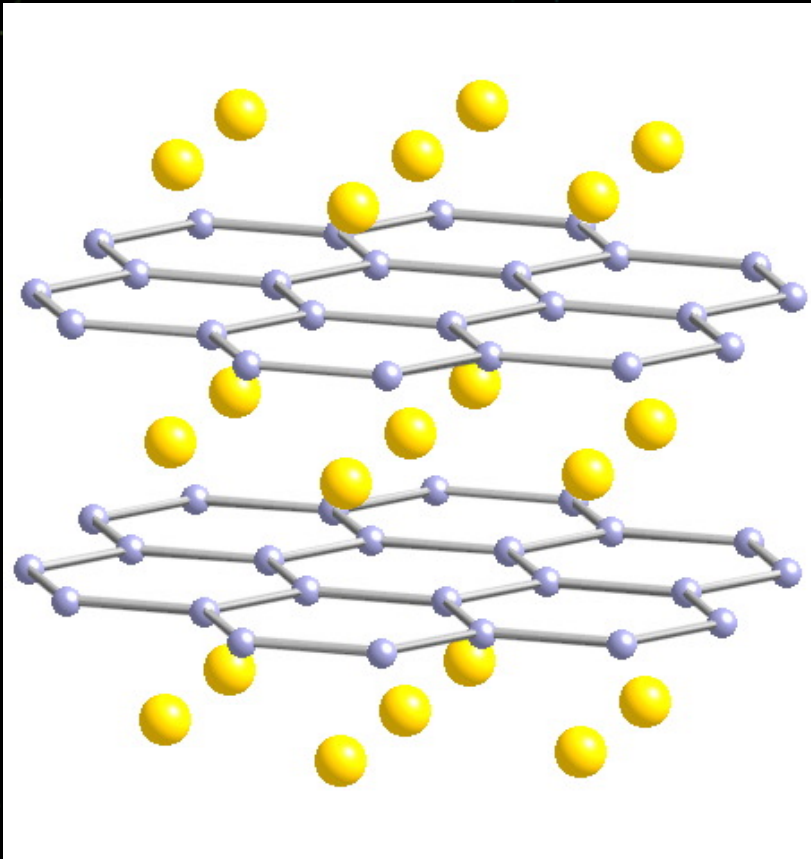

If a crystal has  $N$  unit cells and  $R$  atoms/Cell then it has  $3NR$  Normal Modes

Generally: Consider the unit cell periodicity separately by introducing a “continuous” momentum variable,  $q$ .

->  $3R$  modes for any given  $q$

# MgB<sub>2</sub> As An Example

Layered Material  
Hexagonal Structure

B Layer

B-B Bond is Short  
& Stronger

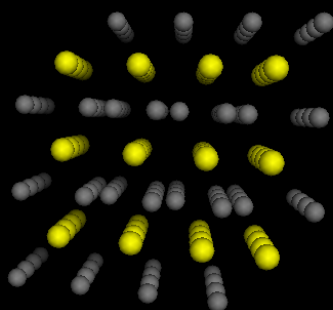

Mg Layer

Mg-Mg Bond is  
Longer & Weaker

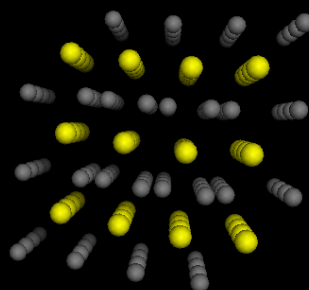

3 Atoms/cell → 9 modes / Q Point

# Acoustic and Optical Modes

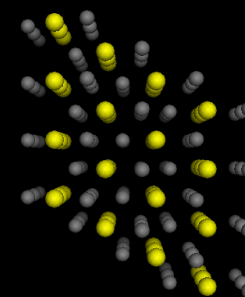

Acoustic Modes are Continuum (Smooth) Modes

LA Mode  
Compression Mode

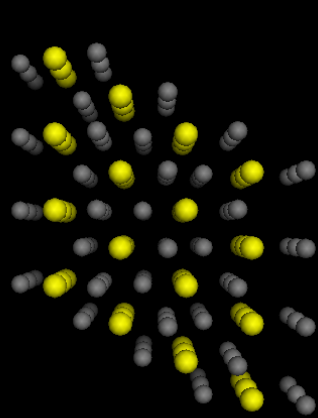

TA Mode  
Shear Mode

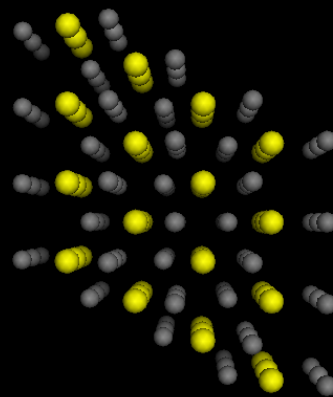

Optical Mode  
Atoms in one unit cell  
move against each-other

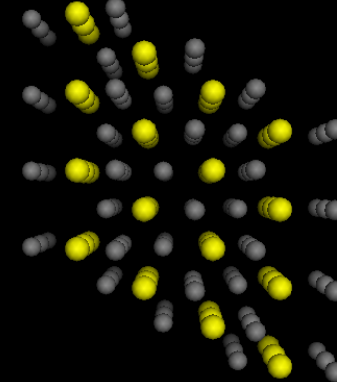

# Dispersion of an Optical Mode

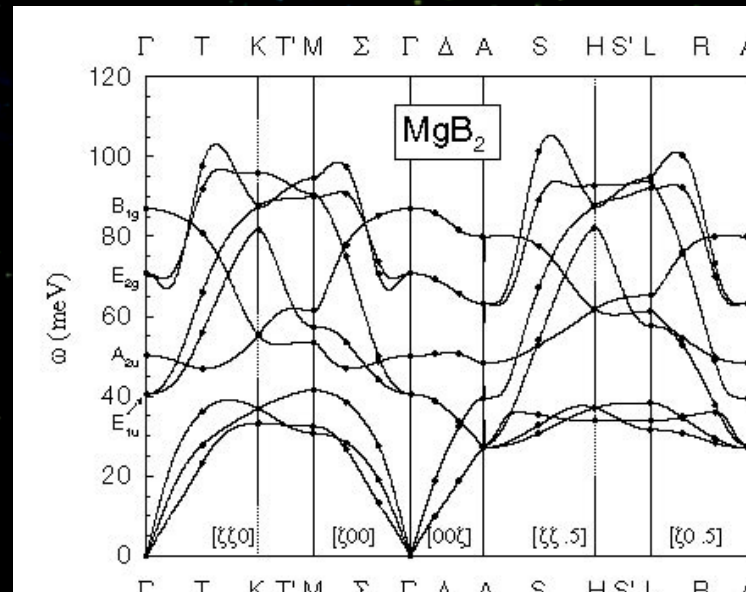

(0 0 0)

(0.25 0 0)

(0.5 0 0)

# Phonons in a Superconductor

Conventional superconductivity is driven by lattice motion.

“Phonon Mediated” - lattice “breathing” allows electron pairs to move without resistance.

Original Picture: **Limited** interest in *specific* phonons...

Now: Lots of interest as this makes a huge difference.

Particular phonons can couple very strongly to the electronic system.

How does this coupling appear in the phonon spectra?

Softening: Screening lowers the energy of the mode  
(abrupt change  $\Leftrightarrow$  Kohn Anomaly)

Broadening: Additional decay channel (phonon  $\rightarrow$  e-h pair)  
reduces the phonon lifetime

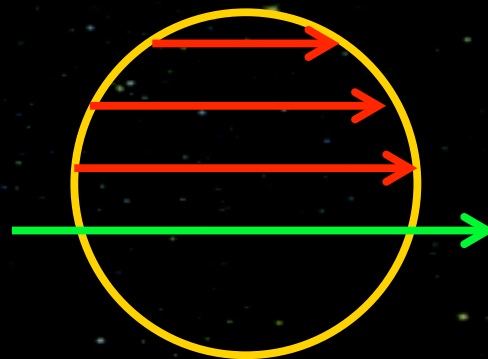

# Electron Phonon Coupling

## & Kohn Anomalies

On the scale of electron energies, a phonon has nearly no energy.  
A phonon only has momentum.

So a phonon can move electrons from one part of the Fermi surface to another, but NOT off the Fermi surface.

Phonon  
Momenta  
 $Q < 2k_F$

Large Momentum  
 $Q > 2k_F$   
Can Not Couple to the  
Electronic system

Fermi Surface  
Diameter =  $2k_F$

# Superconductors

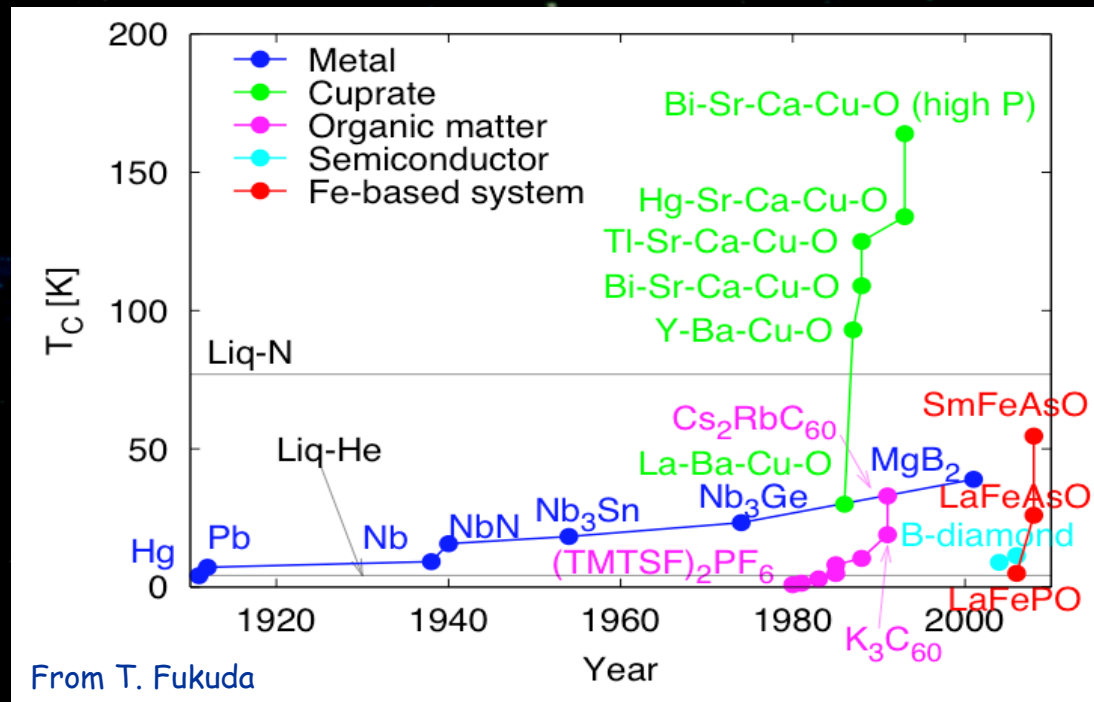

Systems Investigated include

MgB<sub>2</sub>, Doped MgB<sub>2</sub>, CaAlSi, B-Doped Diamond

Hg1201, LSCO, YBCO, LESCO, Tl2212, BKBO, NCCO,

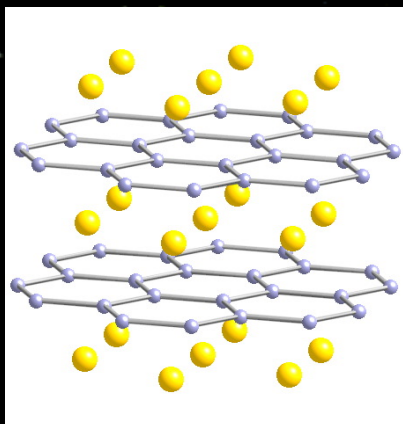

Bi2201, Bi2212, Nickelates, Oxychlorides

Fe-As Systems: LaFeAsO, PrFeAsO, BaKFeAs

Dark Blue Line: Conventional, Phonon-Mediated Superconductors

# MgB<sub>2</sub>

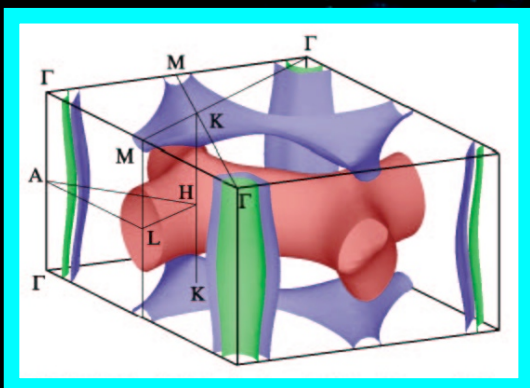

High T<sub>c</sub> (39K)

Nagamatsu, et al, Nature **410**, (2001) 63.

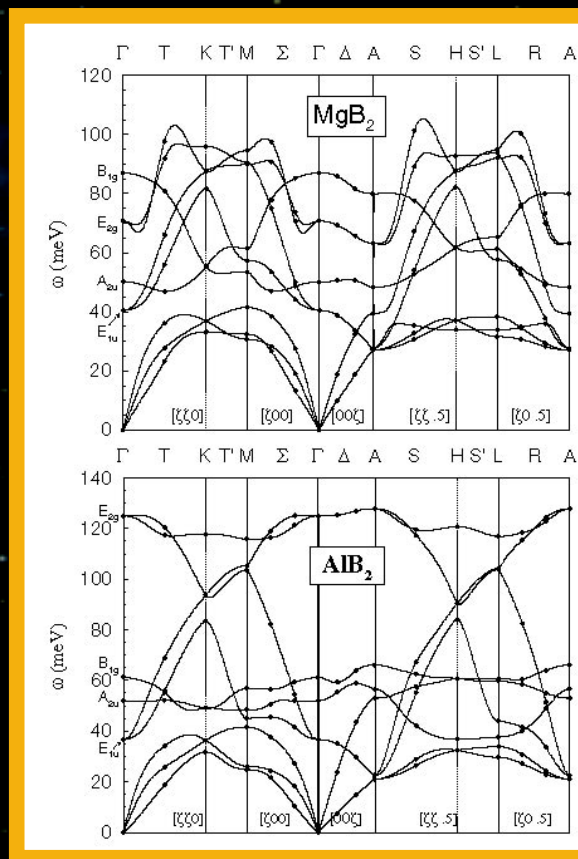

Simple Structure...  
straightforward calculation.

## Electronic Structure

Kortus, et al, PRL **86** (2001)4656

## Phonon Structure

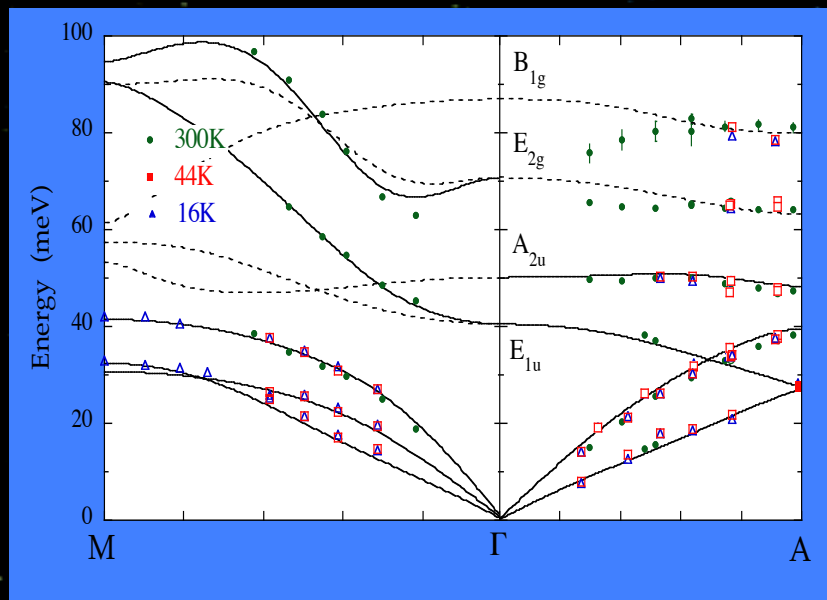

Bohnen, et al. PRL. **86**, (2001) 5771.

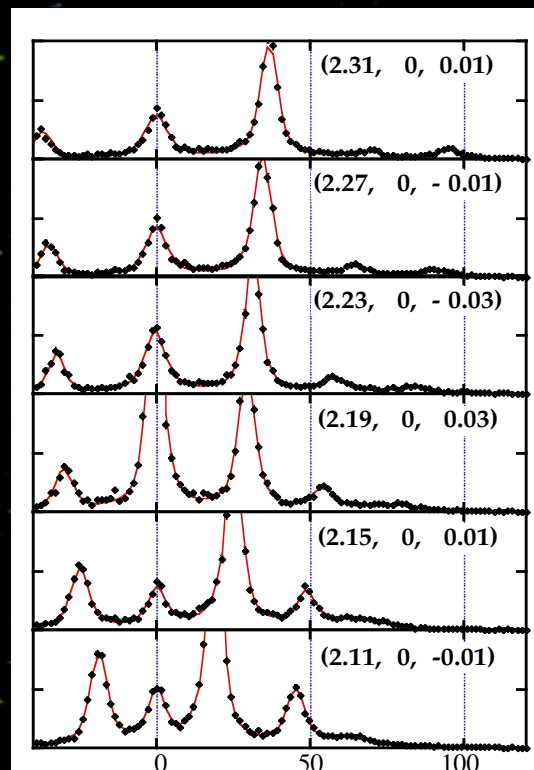

BCS (Eliashberg) superconductor with mode-specific electron-phonon coupling.

# Electron-Phonon Coupling in $\text{MgB}_2$

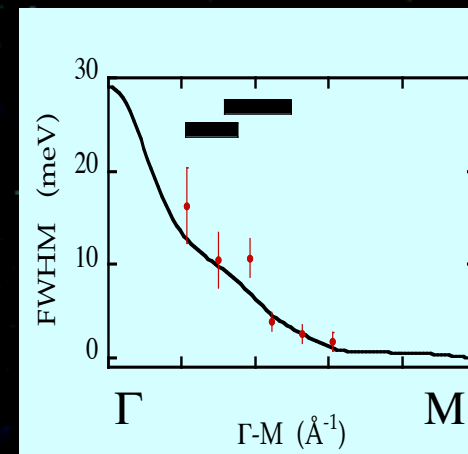

## Dispersion

## Spectra

## Linewidth

Clear correlation between  
linewidth & softening.  
Excellent agreement with LDA Pseudopotential calculation.

PRL 92(2004) 197004: Baron, Uchiyama, Tanaka, ... Tajima

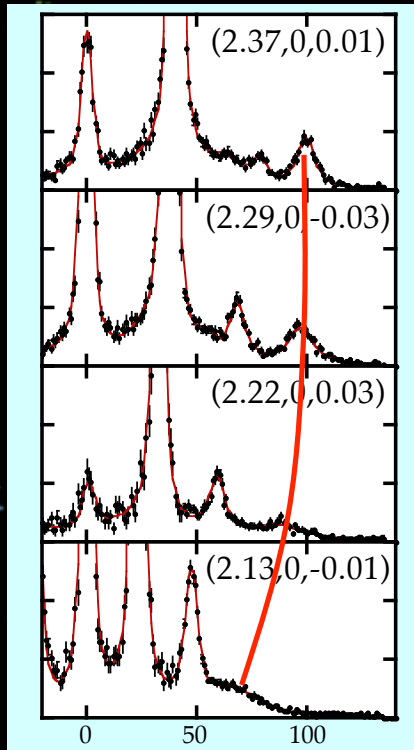

# Carbon Doped $\text{Mg}(\text{C}_x\text{B}_{1-x})_2$

M

2%C,  $T_c=35.5\text{K}$

12.5% C,  $T_c=2.5\text{K}$

$\text{AlB}_2$  (Not SC)

└

Phonon structure correlates nicely with  $T_c$  for charge doping.  
(Electron doping fills the sigma Fermi surface)

# More Superconductors

Similar types of results for  
Mn Doped  $\text{MgB}_2$   
 $\text{CaAlSi}$   
Boron Doped Diamond

Extrapolation to the High  $T_c$  Copper Oxide Materials....

1. Much More Complex
2. Calculations Fail so interpretation is difficult

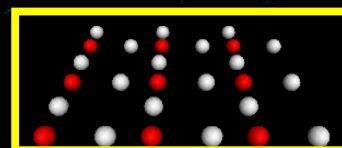

# Phonons in the Cuprates...

Everyone has their favorite mode, or modes, usually focus on Cu-O planes

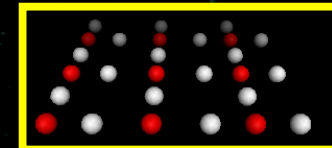

## In-Plane Mode:

Stretching mode

(0 0)

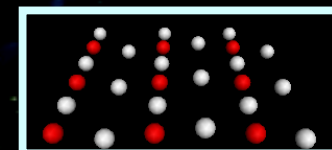

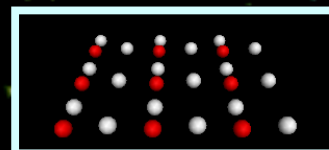

(0.5 0)

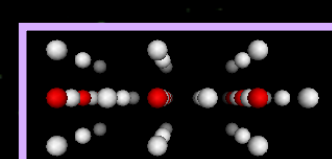

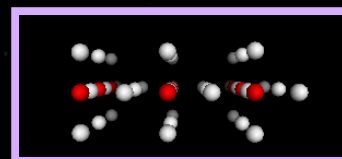

## Out of Plane Modes:

Buckling Mode

Apical Mode

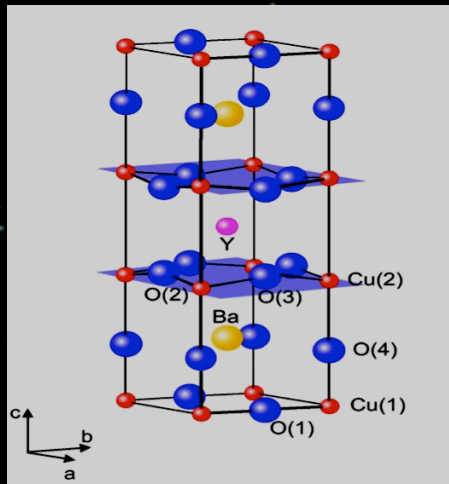

At the level of phonon spectra, the anomaly of the Bond Stretching Mode is very large

# Copper Oxide Superconductors Remain Challenging...

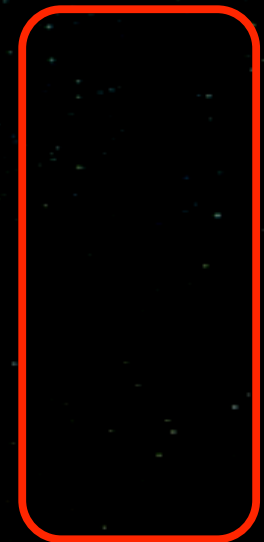

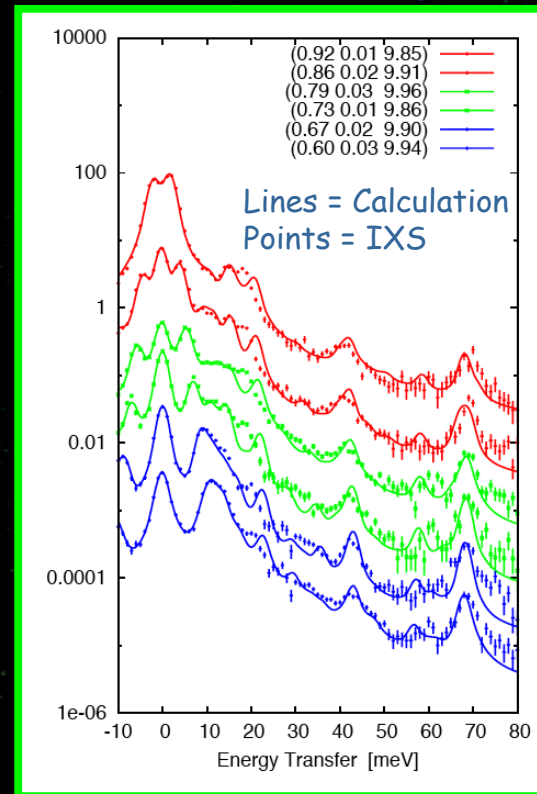

De-Twinned YBCO:  
 $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$

$T_c = 91 \text{ K}$

C-axis modes

In-Plane Modes

Beautiful Agreement

Problems

Shows Bond Stretching Anomaly  
Is Huge ( $\gg$  Buckling Anomaly)

Compare IXS to Calculation

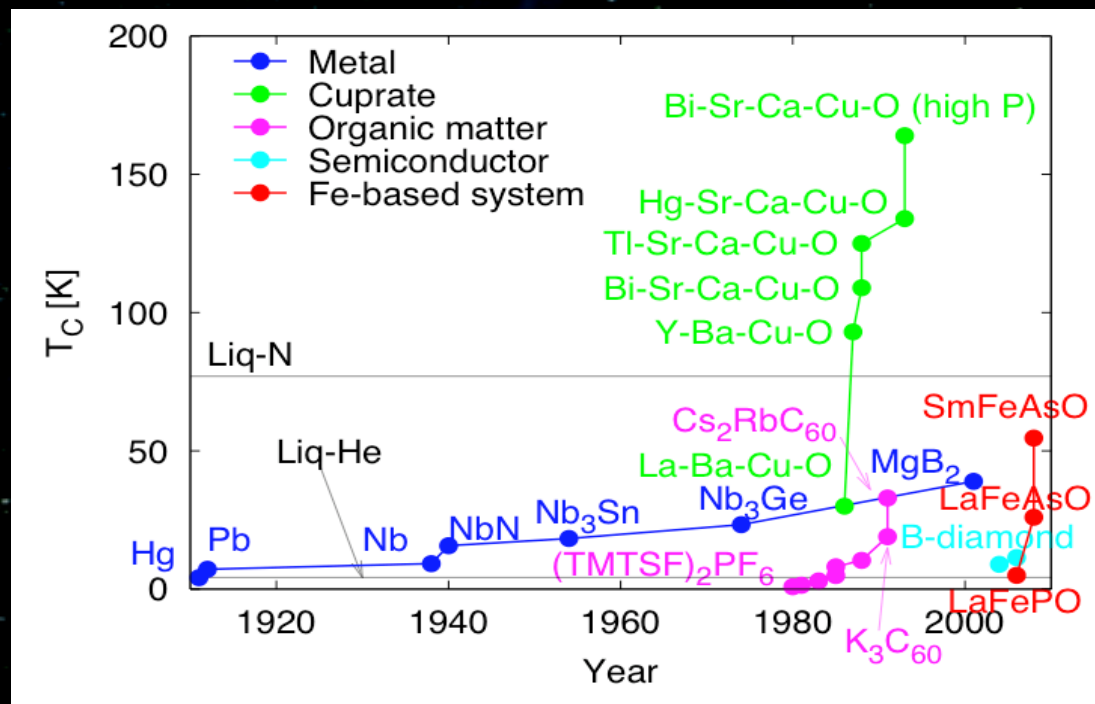

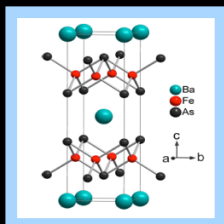

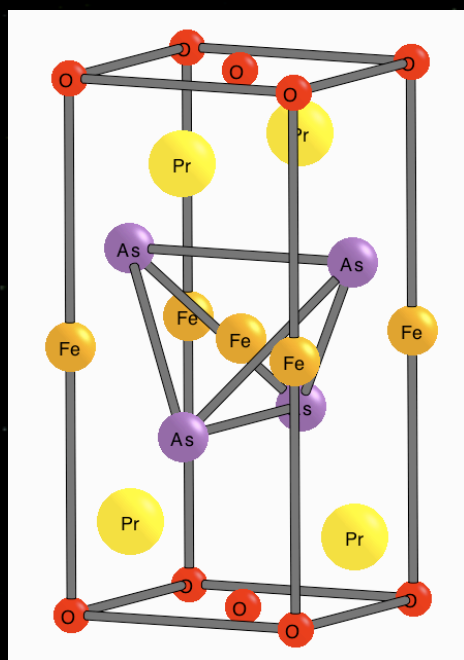

At low T ( $\sim 30 \text{ K}$ )

Bohnen, et al.

AQRB @ AOFSSR Cheiron School 2013

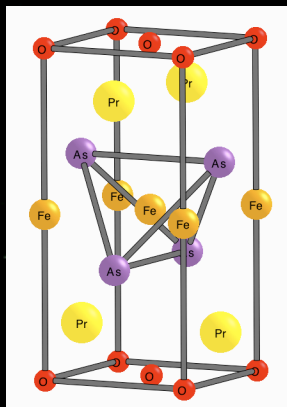

# Iron-Pnictide Superconductors

High- $T_c$  demonstrated February 2008 (Hosono's group)  
( $T_c$  saturated within months...)

Several families: Fe with Tetrahedral As (or Se)  
Proximity to Magnetic Order

# Phonons in the Iron Pnictides

1111 Materials  $\rightarrow$  8 Atoms/cell  
 $\rightarrow$  24 Modes (6 mostly oxygen)

Magnetism  $\rightarrow$  16 Atoms / 48 Modes

No ab mirror plane  
 $\rightarrow$  Complex motions appear quickly  
as one moves away from gamma.

Phonon response, in itself, is remarkably plain:

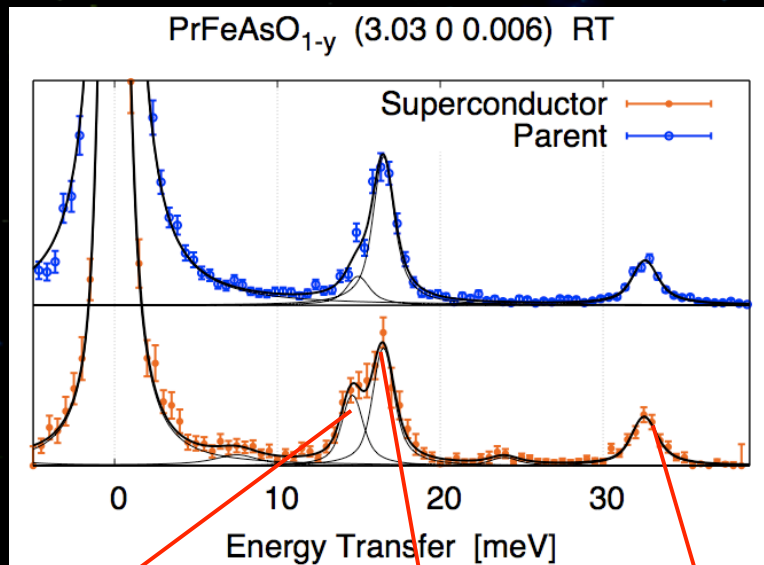

NO very large line-widths

NO obvious anomalies

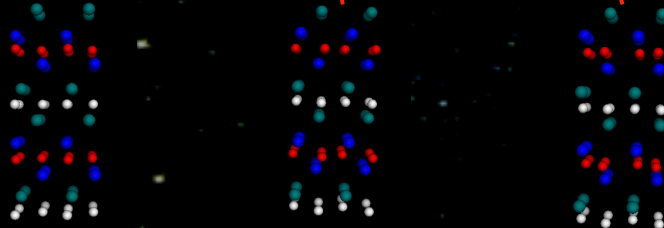

NO asymmetric Raman lines

# Some Examples of Measured Spectra:

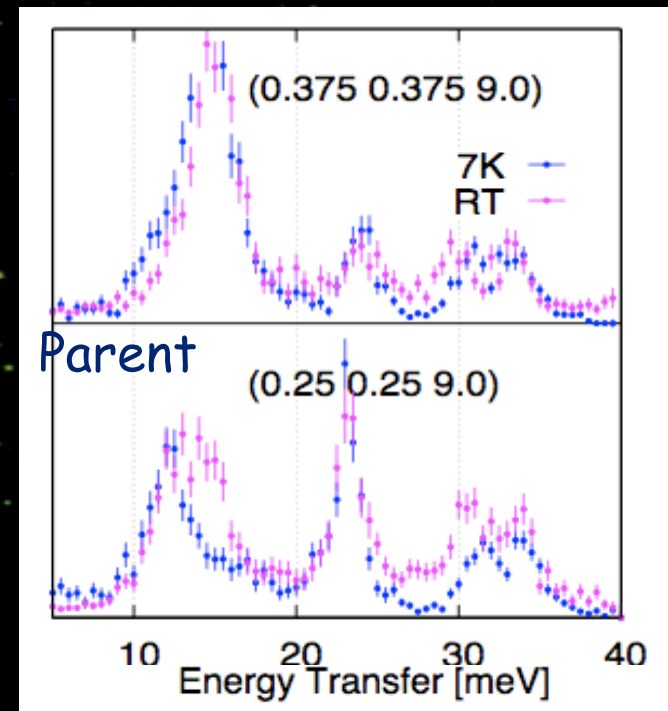

## In-Plane

Estimate  
of mode  
motions  
based on  
calc

## C-axis

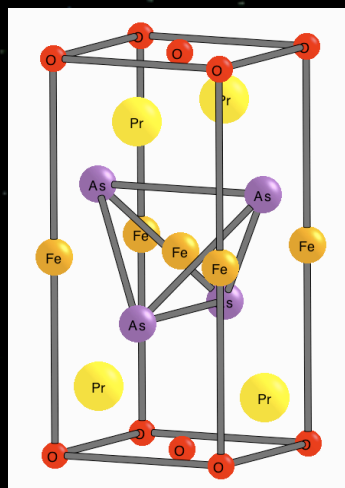

Clear differences in measured spectra (with doping, temperature)  
→ interpretations requires modeling...

# Basic DFT (GGA) for PrFeAsO

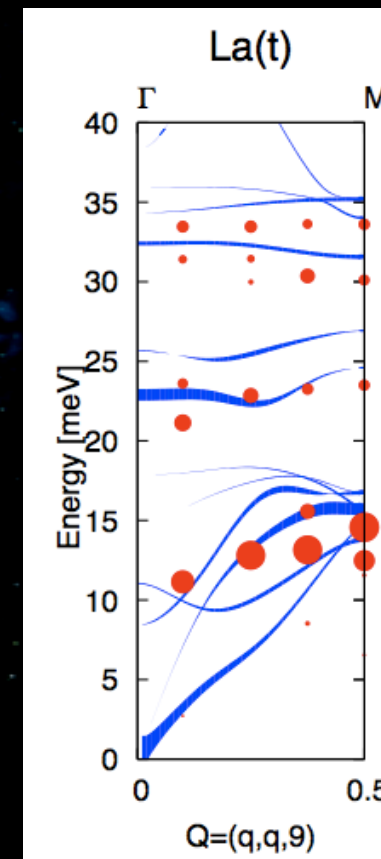

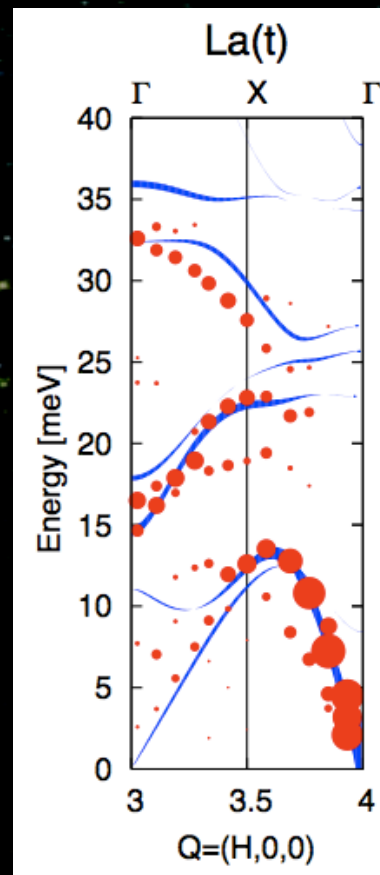

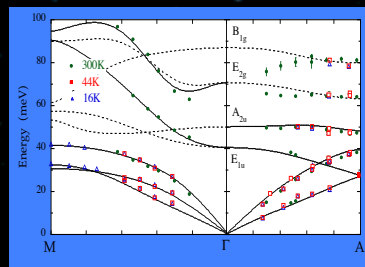

(No Magnetism)

Some agreement, but details are poor

Also, fails to get correct As height above the Fe planes.

Fe-As Bond Length  
Expt: 2.41 Å  
GGA: 2.31 - 2.33 Å

**A Better Model is Needed**

Symbol size: Measured Intensity  
Line Thickness: Calculated Intensity

# Different Models:

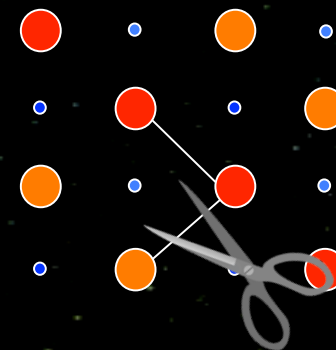

Original: Straight GGA for Tetragonal stoichiometric PrFeAsO

O<sub>7/8</sub>: Super cell 2x2x1 with one oxygen removed  
and softened Fe-As NN Force constant  
(31 atoms/prim cell, Tetragonal, No Magnetism)

Magnetic Orthorhombic: LSDA for LaFeAsO with  
stripe structure of De la Cruz (16 atoms/prim. cell, 72 Ibam)

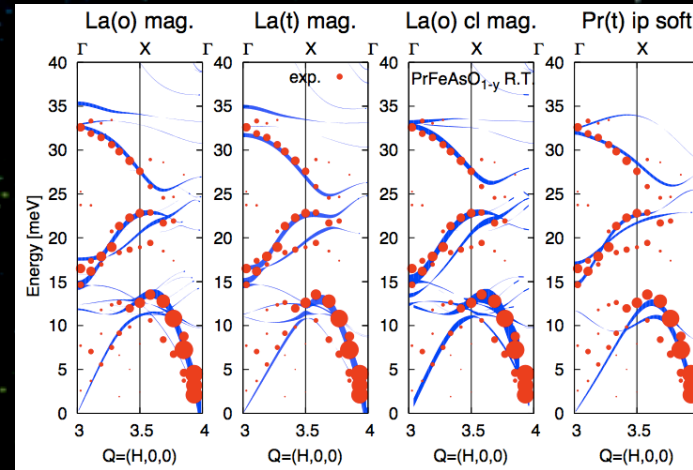

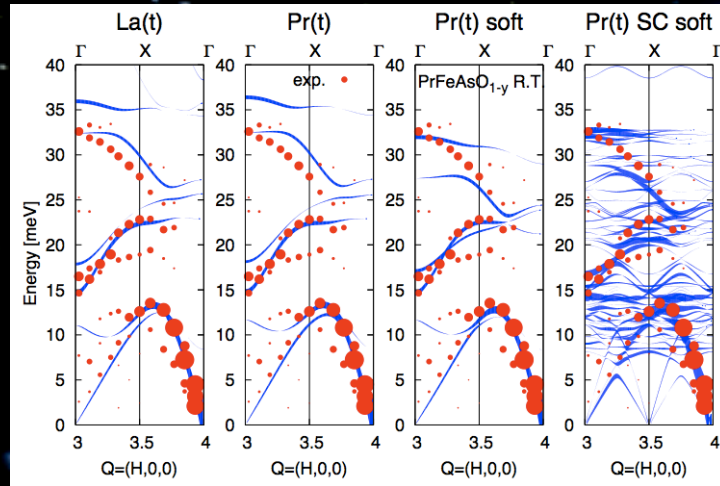

Magnetic Tetragonal: LSDA for LaFeAsO with stripes  
Force a=b (to distinguish effects of structure vs magnetism)

- ★ Soft: As “Original” but soften the FeAs NN Force constant by 30%
- ★ Clipped: Mag. Ortho. with cut force constant
- ★ Soft IP: “Original” but soften FeAs NN *In Plane* components

# Compare dispersion with various models

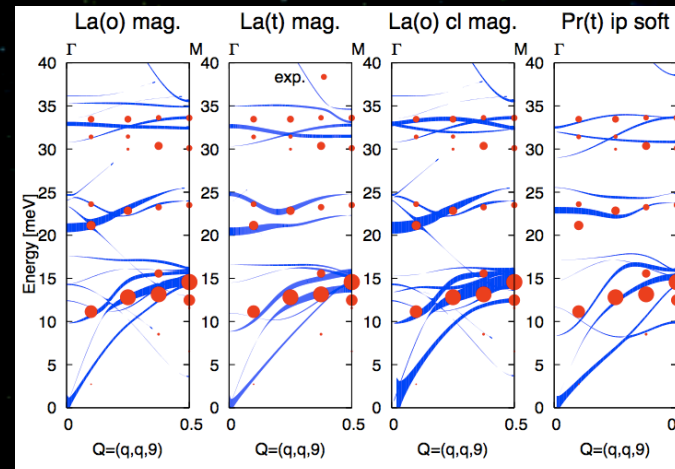

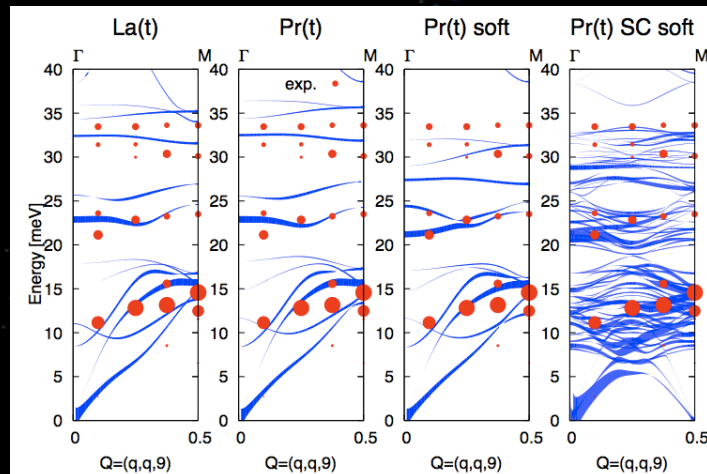

In-Plane

Red =  
Data (SC)

Blue =  
Calc.

C-axis

Size:  
Intensity

Over all: Better fit with magnetic calculations  
And best fit with either "clipped" or "IP Soft" model

Of the straight ab-initio calculations, magnetic models do better than non-magnetic due to softening of ferrmagnetically polarized modes  
However, they get details wrong, including too high an energy for AF polarized modes & predicting splitting that is not observed

Of the modified calculations, the in-plane soft generally seems best, but still data-calc difference are larger than doping/T effects.

Many people have suggested some sort of fluctuating magnetism, especially when magnetic calculations were seen to be better than non-magnetic calcs for the (non-magnetic) superconducting materials.

However, phonon response of parent and SC are nearly the same, and it seems unlikely that fluctuating magnetism is the answer in the parent material which shows static magnetism.

Still some missing ingredient(s) in the calculation  
-> Interpretation Difficult

# Towards A Better Model?

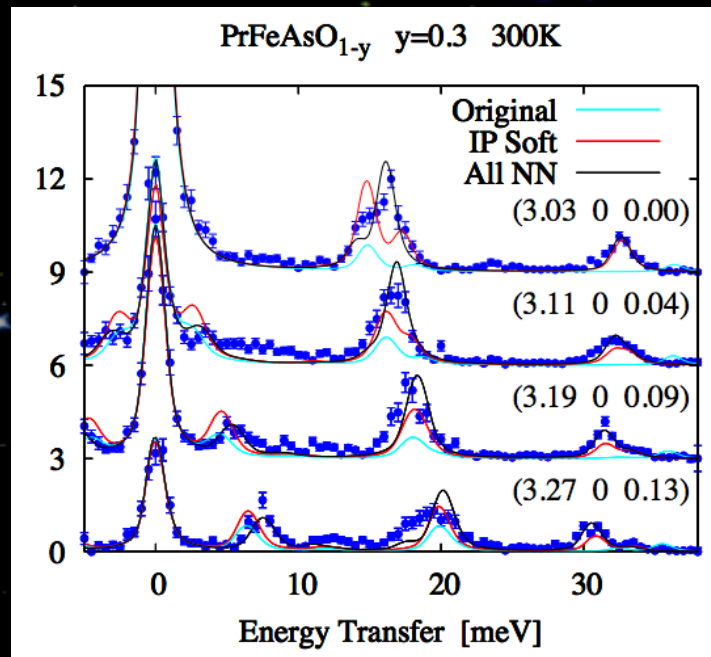

Fitting of full spectra: intensity vs energy transfer.

Zeroth Approximation: All Samples are the Same  
Doping and Temperature Dependence are Weak

Differences between samples is generally much smaller  
than between any calculation and the data

-> Fit all spectra to a common model  
and then fit subsets of the data to determine  
effects of doping or phase transitions.

# Fit Full Spectra

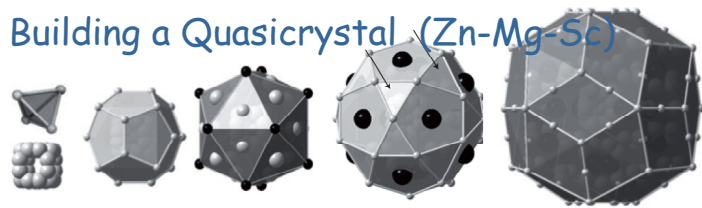

In-Plane Soft is  
*NOT* bad but also  
But also *NOT* great.

Some improvement by  
allowing parts of nearly all  
NN bonds to change.

# Phonons in a Quasicrystal

Mostly like a solid but some glassy character.

Building a Quasicrystal (Zn-Mg-Sc)

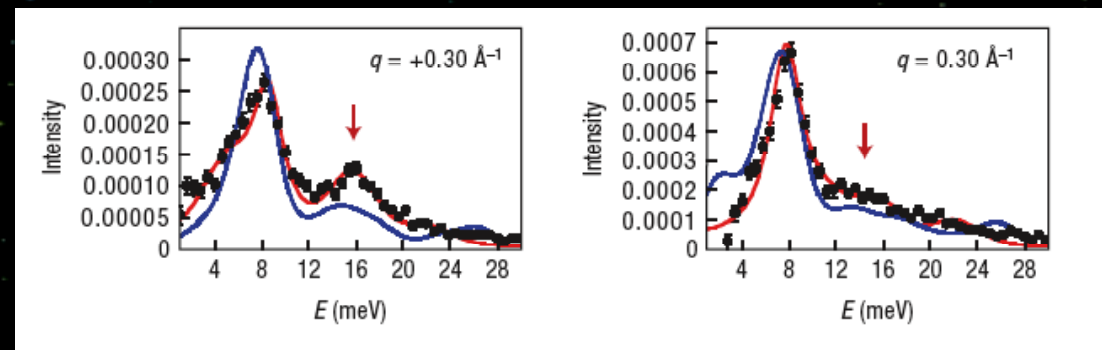

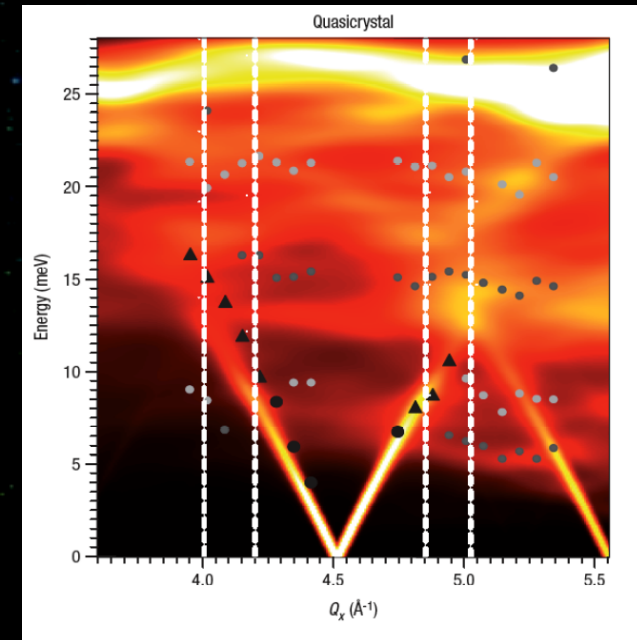

Periodic (BCC) -> Crystalline Approximant  
Aperiodic -> Quasicrystal

Compare to crystalline approximant &  
Simulation (2000 atoms/cell)

General Trend: Blurring out  
past a cutoff energy  
“Pseudo-Brillouin” zone size

De Boissieu, *et al.*  
Nature Materials, Dec 2007

Red: Fits, Blue: Simulation

AQRB @ AOFSSR Cheiron School 2013

# Ferroelectrics

Develop spontaneous polarization over macroscopic ( $> \sim \mu\text{m}$ ) domains when  $T$  is below the ferroelectric transition temperature ( $T_0$ ). The origin is a displacement (off-centering) of ions. This is switchable by an external (electric) field.

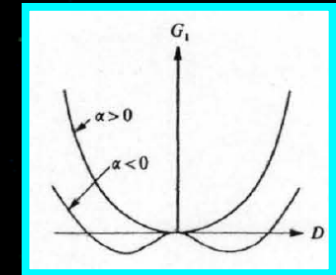

Zeroth Approximation  $\rightarrow$  Two types of transitions

"Displacive" transition where there is a "continuous" below  $T$

"Soft Mode" transition Examples:  $\text{BaTiO}_3$ ,  $\text{KTaO}_3$ ,  $\text{Gd}(\text{MoO}_4)_3$

Soft Mode  
Nomenclature

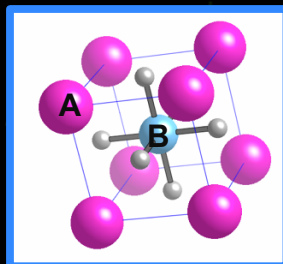

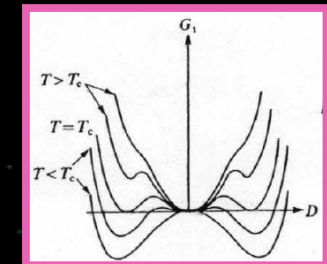

Ferrodistoritive transition involves softening of gamma point mode (ferroelectric modes)  
Antiferrodistoritive involves softening of zone boundary mode (unit cell size increases)

Lines & Glass

"Order-Disorder" transition where displacements occur first metastably and then condense. No soft mode.

Examples  $\text{KH}_2\text{PO}_4$  (KDP),  $\text{NaNO}_2$ , Organics

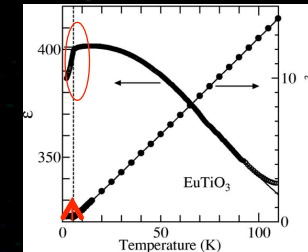

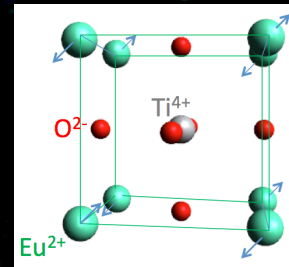

Perovskite structure ( $\text{ABO}_3$ ) popular as it is *relatively* simple and the cubic structure is inherently unstable.. Why?

(3 atoms & one lattice constant)

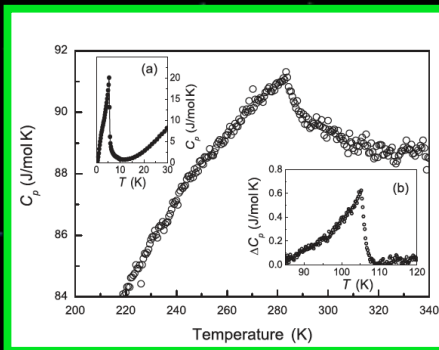

# Multiferroic $\text{EuTiO}_3$

Perovskite - Similar to  $\text{SrTiO}_3$

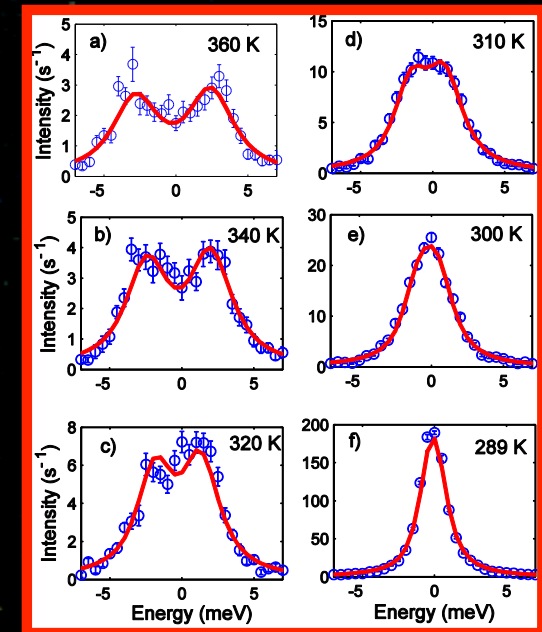

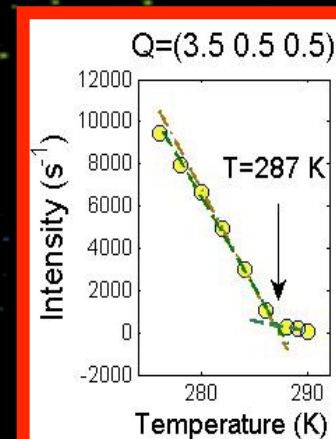

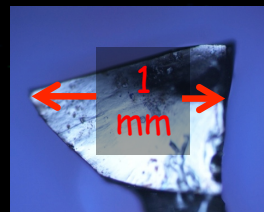

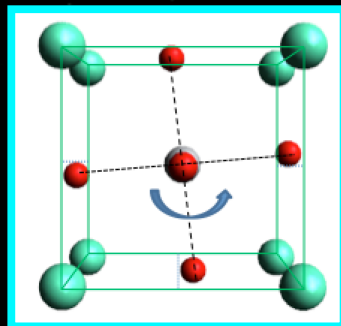

But with magnetism & coupling of magnetic & dielectric response

Katsufuji & Takagi, PRB, 2001

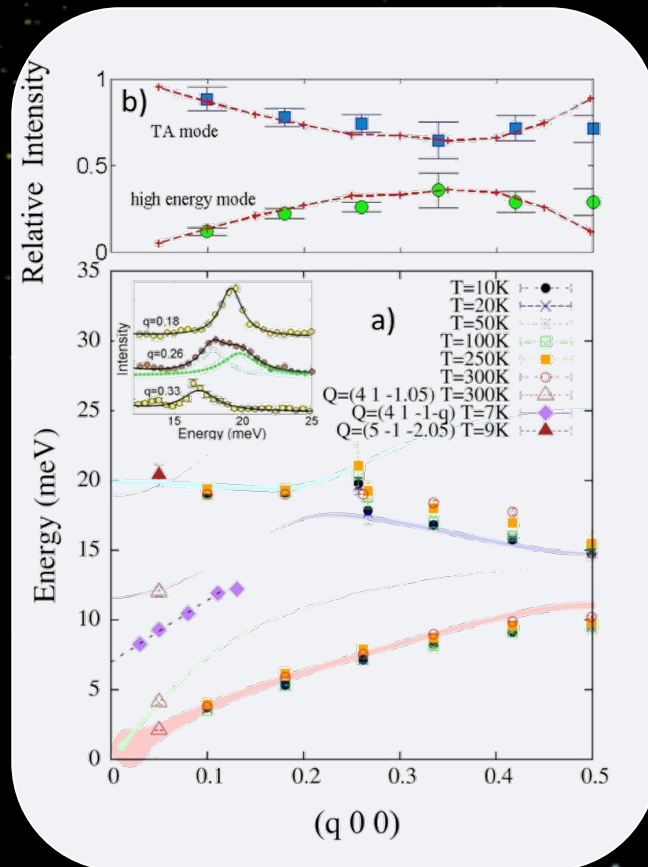

Phase transition just below RT - putative rotation oxygen octahedra. Calculations say disorder-order. Bussman-Holder, PRB, 2011

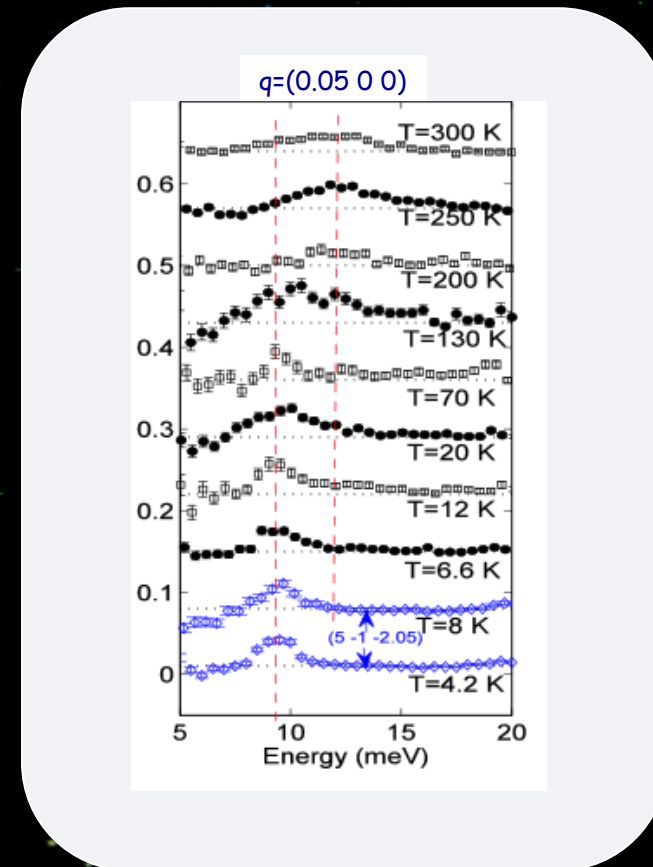

IXS -> Phonon Softening -> Displacive

# Dispersion, Shell Model, & Approaching $T_N$

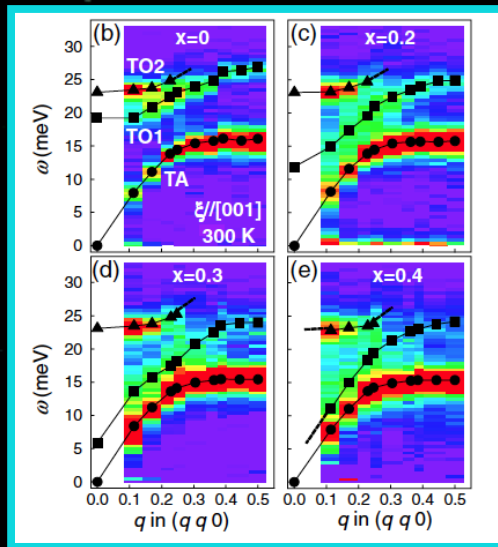

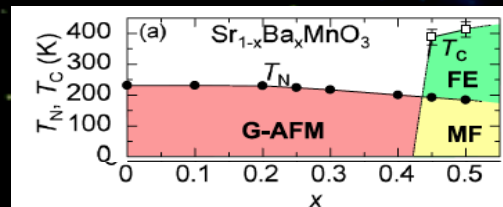

Shell model  $\rightarrow$  Good agreement  
Suggests "soft" mode has Slater  
character.

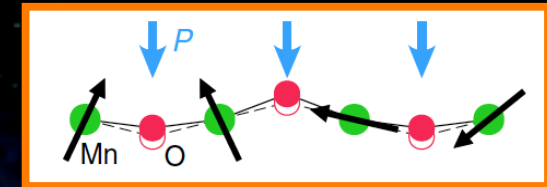

"Softening" (or weight shift) as  $T$  is  
reduced toward  $T_N$  consistent with  
gradual change in dielectric response

# Multiferroics

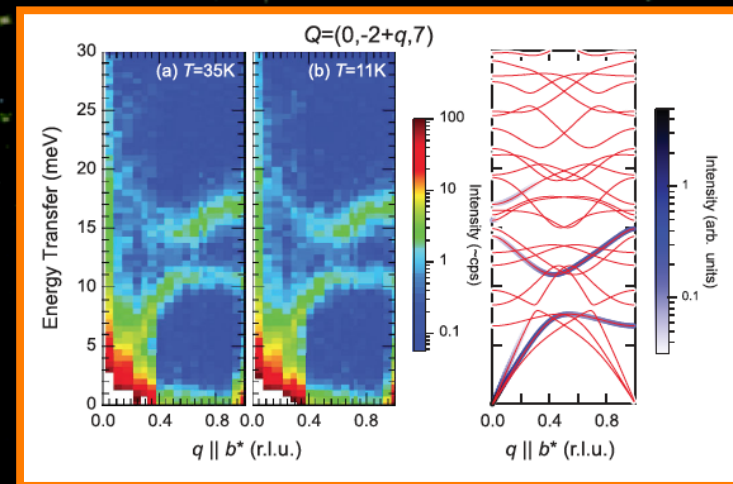

Classical ferroelectric soft mode

Sakai, et al. PRL 2011 (Tokura-lab)

Cycloidal spin structure coupled to development of polarization below 28K

No observed phonon softening may suggest a different (magnetic) driving force

Kajimoto, et al. PRL 2009 (Tokura-lab)

# IXS under High Pressure

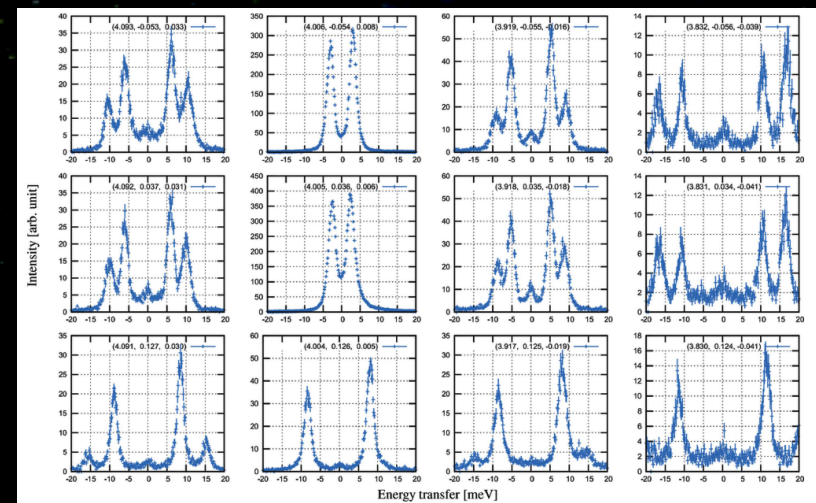

General Viewpoint: Just another thermodynamic variable.

Specific: elastic properties in extreme (geological) conditions based on IXS sound velocity measurements

Often: Just want the sound velocity  
Precision/Accuracy 0.2/0.8% using  
Christoffel's Eqn & 12 Analyzer Array  
H. Fukui, et al., JSR

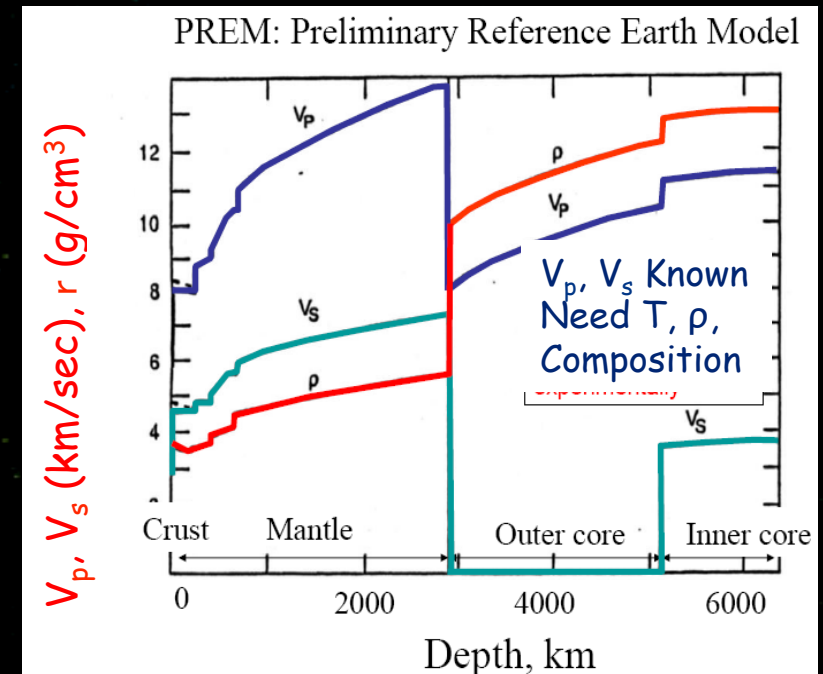

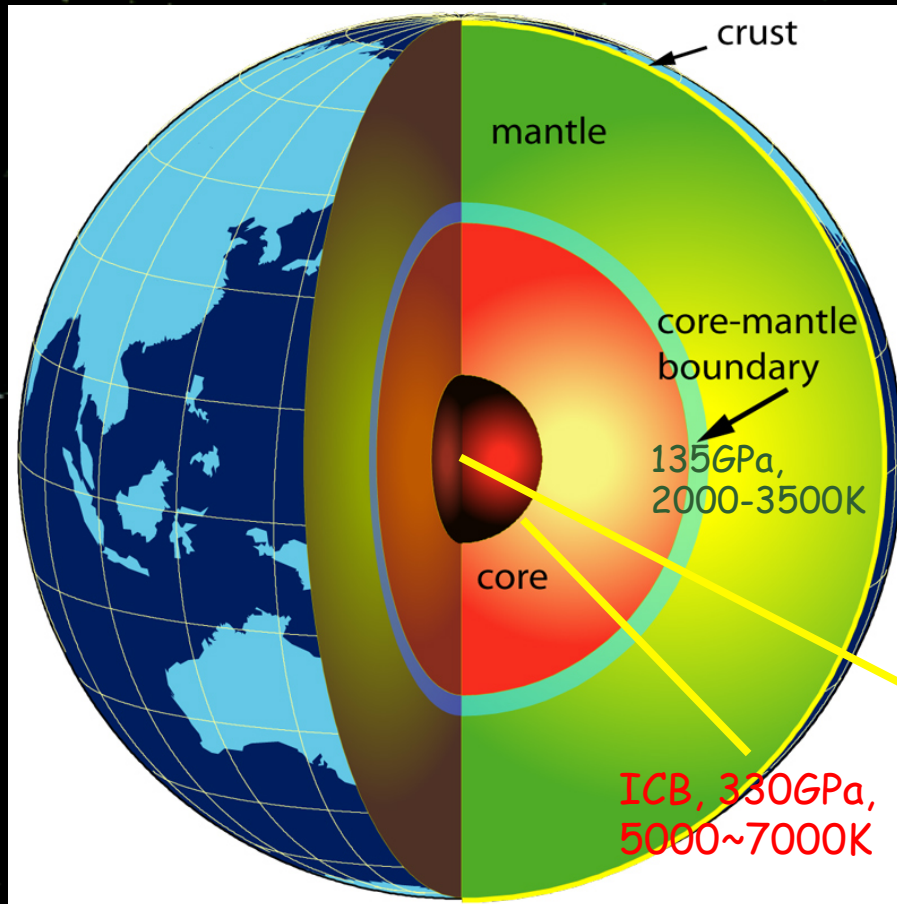

~1 Order Improvement in Precision  
Over Previous IXS

MgO Single Crystal in Ambient Conditions

One Scan with 12-Analyzers

# High Pressure & Temperature for Geology

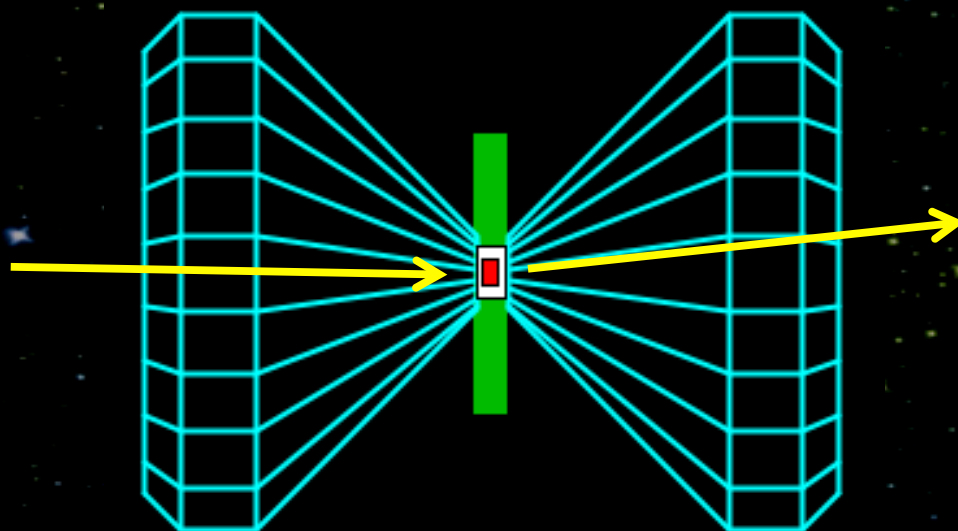

Earth's Center, 365 GPa  
6000~8000 K

Needed: Lab measurements relating  $T$ , Density & Composition to  $V$

# Diamond Anvil Cells

$P > 200 \text{ GPa}$   
 $T > 2000\text{K}$  (Laser Heating)

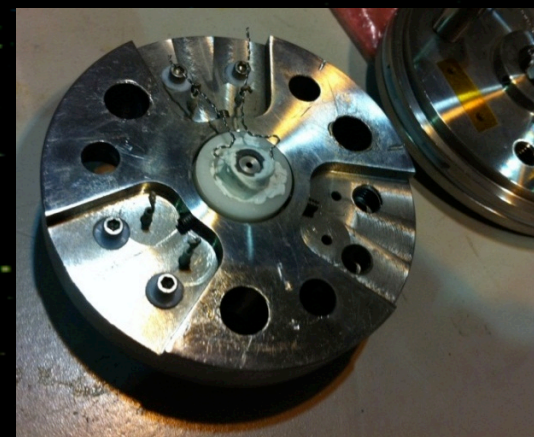

So far with IXS:  
 $170 \text{ GPa}$  or  $1800\text{K}$

Diamonds:  $2 \times 1.5\text{mm}$  Thk  
 Sample:  $\sim \Phi 20 \mu\text{m} \times 5\mu\text{m}$  Thk  
 Also Gasket & Pressure Medium  
 $P$  increases  $\rightarrow$  Smaller Sample & Gasket Hole

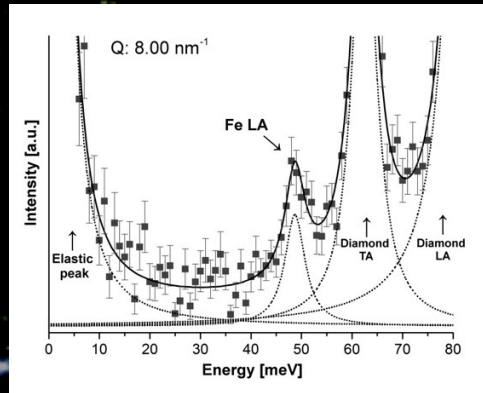

Std Cell  
 Laser

Cell with Internal Heating

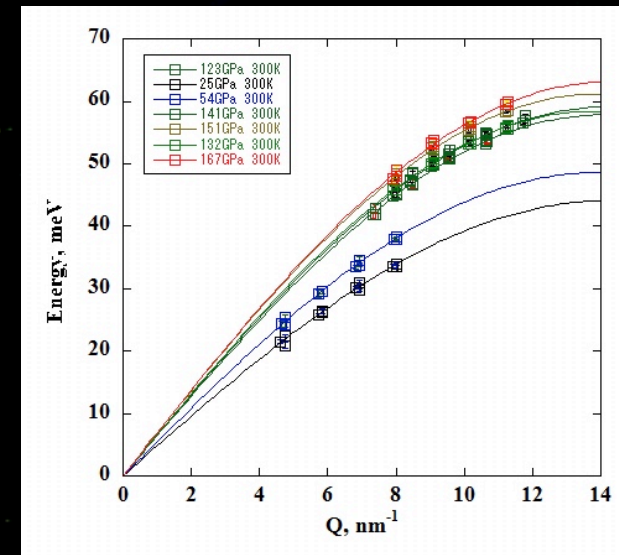

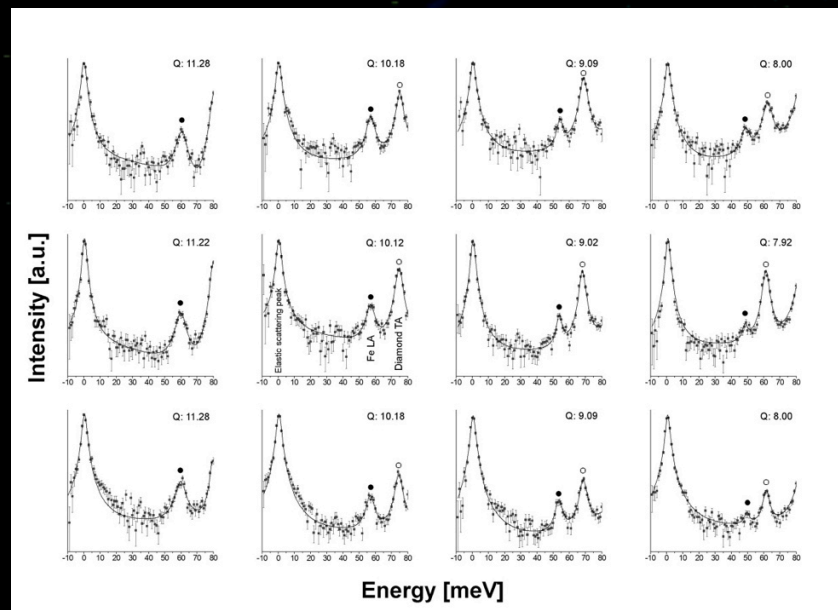

Small samples, Signal low, Poor signal to noise

# IXS Data for Iron at 167 GPa

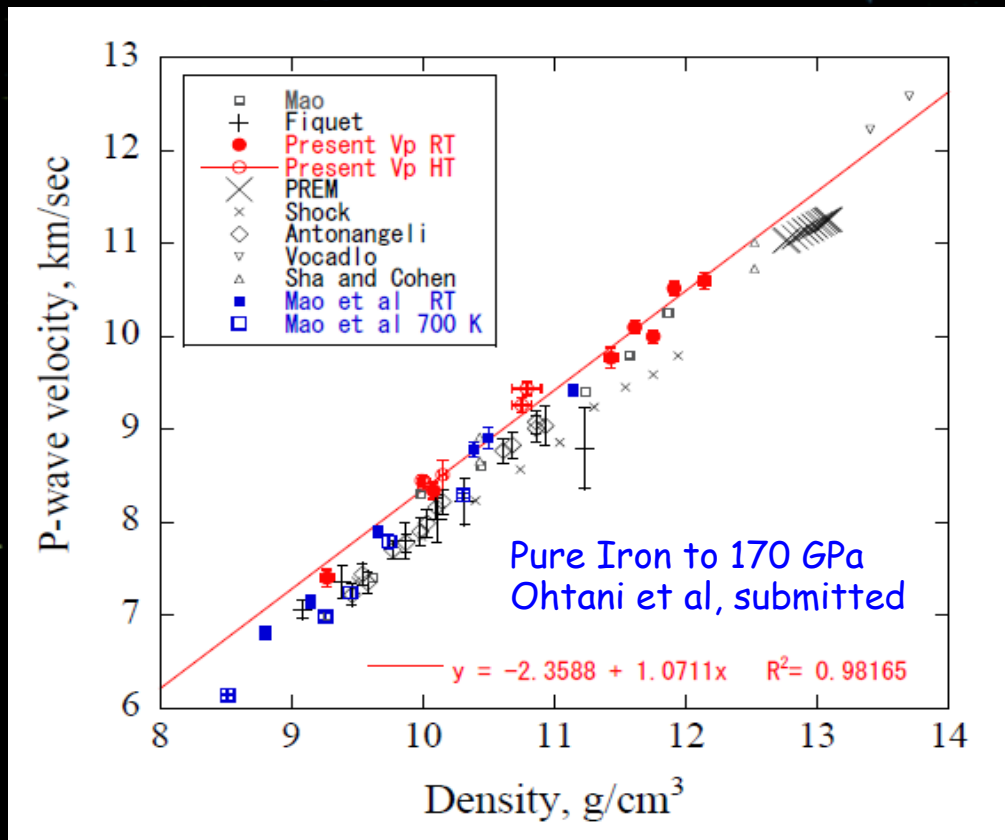

Very clear iron peak, but significant backgrounds  
(Note diamond background can be tricky  
→ careful orientation is required)

Sine fit gives velocity ( $V_p$ )

# Sound Velocity in Pure Iron

Birch's Law: Linear relation between density and velocity.

SIMPLE, in principle

But 3 Facilities -> mostly different results

SP8 is faster than ESRF and similar to APS  
ESRF recently became faster than before

T-Dependence:  
APS is sensitive.  
SP8 and ESRF are not.

Discussion is needed -> workshop

# Novel Uses of The Phonon Intensity

Phonon Cross Section:

$$\left( \frac{d^2\sigma}{d\Omega dE} \right)_{\mathbf{k}_1 \epsilon_1 \rightarrow \mathbf{k}_2 \epsilon_2} = \frac{k_2}{k_1} r_e^2 \left| \epsilon_1^* \cdot \epsilon_2 \right|^2 S(\mathbf{Q}, \omega)$$

$$S(\mathbf{Q}, \omega)_{1p} = N \sum_{\substack{\mathbf{q} \\ \text{1st Zone}}} \sum_{\substack{j \\ \text{3r Modes}}} \left| \sum_{\substack{d \\ \text{Atoms / Cell}}} \frac{f_d(\mathbf{Q})}{\sqrt{2M_d}} e^{-W_d(\mathbf{Q})} \mathbf{Q} \cdot \mathbf{e}_{\mathbf{q}jd} e^{i\mathbf{Q} \cdot \mathbf{x}_d} \right|^2 \delta_{(\mathbf{Q}-\mathbf{q})\mp} F_{\mathbf{q}j}(\omega)$$

$$F_{\mathbf{q}j}^{Harmonic}(\omega) = \frac{1}{\omega_{\mathbf{q}j}} \left[ \langle n_{\omega_{\mathbf{q}j}} + 1 \rangle \delta(\omega - \omega_{\mathbf{q}j}) + \langle n_{\omega_{\mathbf{q}j}} \rangle \delta(\omega + \omega_{\mathbf{q}j}) \right]$$

In principle, the phonon polarization is complex, but in some cases, it can be simple, or smooth, letting one get information about

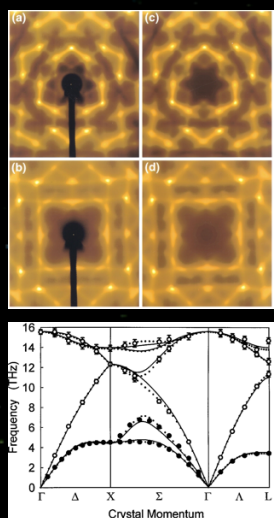

e.g. the form factor from frequency resolved measurements or sharp frequency changes from integrated measurements

# Using Thermal Diffuse Scattering (TDS)

Phonon Intensity  $\sim 1/w \rightarrow$  In simple materials can use intensity to gain insight about phonon frequencies

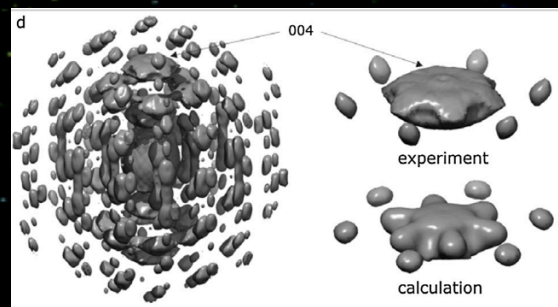

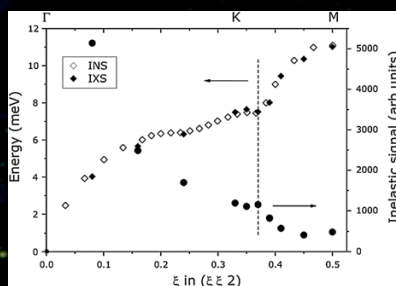

Long history... at least to Colella and Batterman PR 1970 (Va dispersion)

More sensitive  $\rightarrow$  See Kohn anomalies when phonons span the Fermi surface

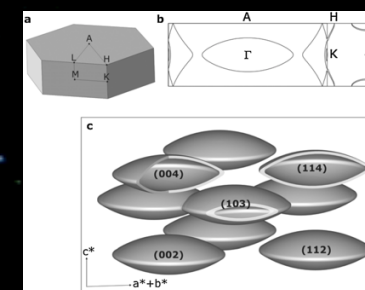

TDS from Silicon

Holt, et al, PRL 1999

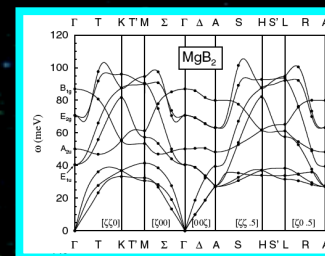

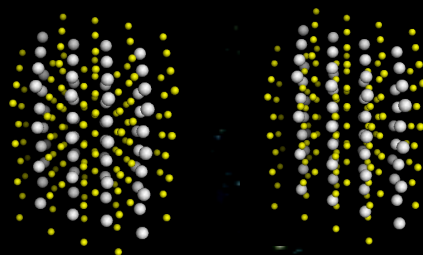

Zn, Bosak et al, PRL 2009

Detailed Phonon/FS behavior in SIMPLE materials  
More generally very useful, but not so detailed  
... use it to learn where to look...

# Atomic $\rightarrow$ Electronic Dynamics

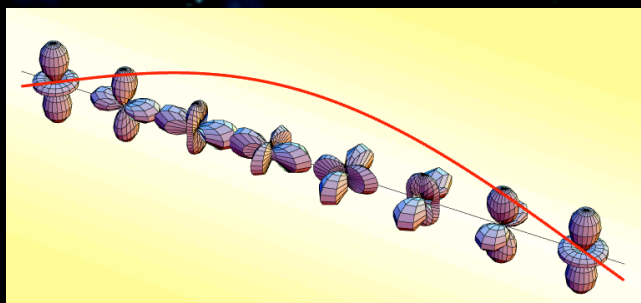

Atomic  
Dynamics

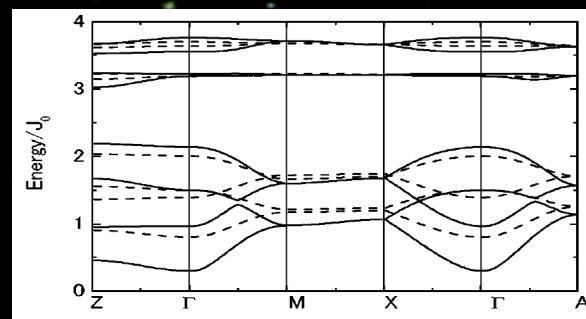

Correlated atomic motions (phonons) play a role in many phenomena  
(e.g. superconductivity, CDWs, phase transitions, thermoelectricity, magneto-elastic phenomena etc)

Electronic excitations similar: Orbitons...?

Orbiton Movie  
S. Maekawa

1 electron  $\rightarrow$  Very Weak

Calculated Orbiton Dispersion  
Ishihara

Key is to see momentum dependence (dispersion).

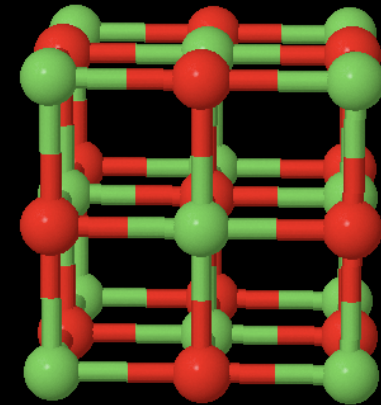

# d-d Excitations in NiO

First something simple...

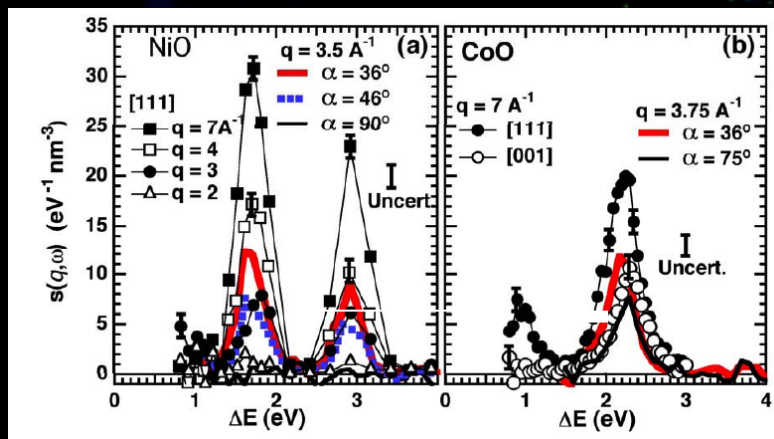

There exist well-defined excitations in the charge transfer gap of NiO  
Antiferromagnet ( $T_N$  523K), (111) Spin order

## Long and Distinguished History

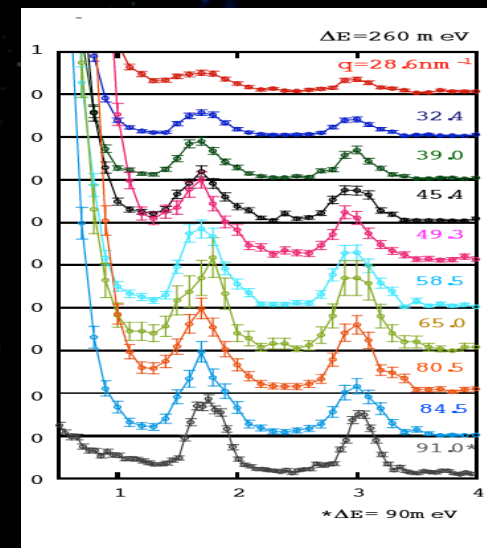

First (resonant) IXS experiments (Kao, et al)

## Non-Resonant IXS, $\Delta E \sim 300$ meV

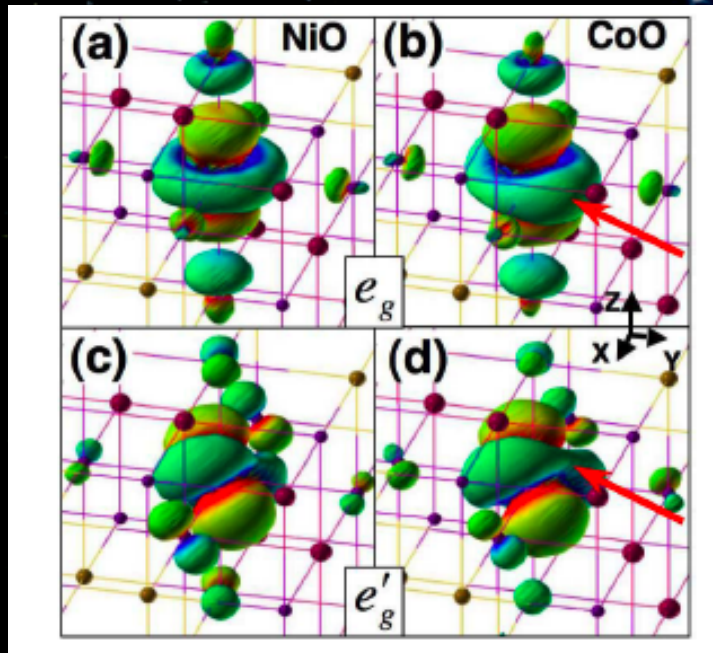

Larson, et al., PRL 99 (2007) 026401

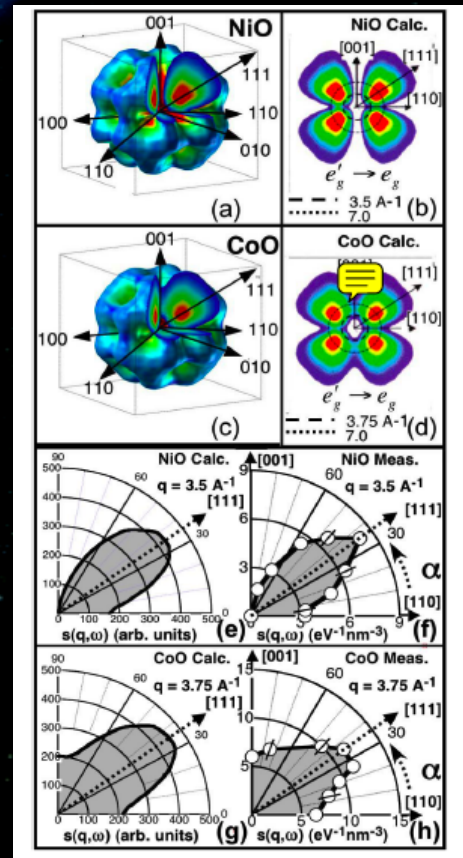

Cai, et al, BL12XU, Unpublished

# Orientation Dependence

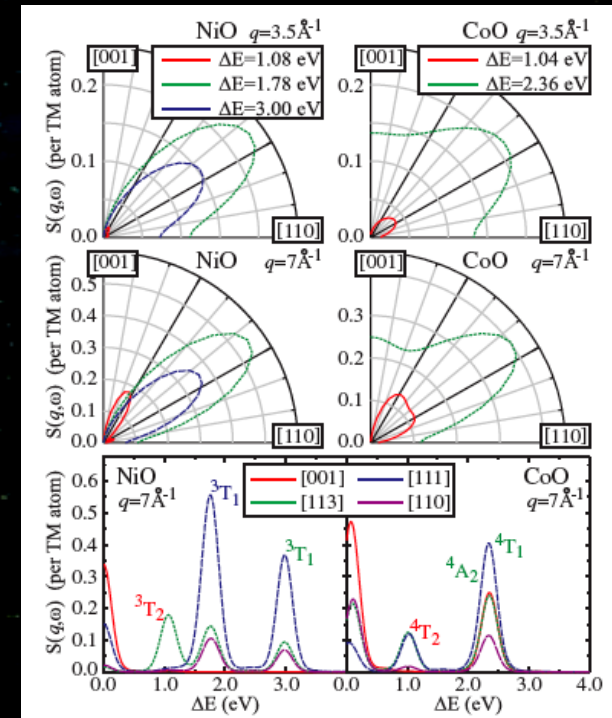

## Orbitals

Results of Wannier function analysis of LDA+U calcs of Larson *et al*/PRL (2007)

## Scattered Intensity

Cluster calculations  
Haverkort, *et al* PRL (2007)

# First High Resolution Experiment

7 meV resolution at 1800 meV energy transfer

Cleaner “Optical Spectroscopy” due to

1. Non-resonant interaction  $S(Q, \omega)$
2. Large  $Q$  &  $Q$  dependence
  - > selects multipole order.
  - > atomic correlations.

Linewidth -> information about environment  
Spin fluctuations  
Lattice interactions (Franck-Condon)

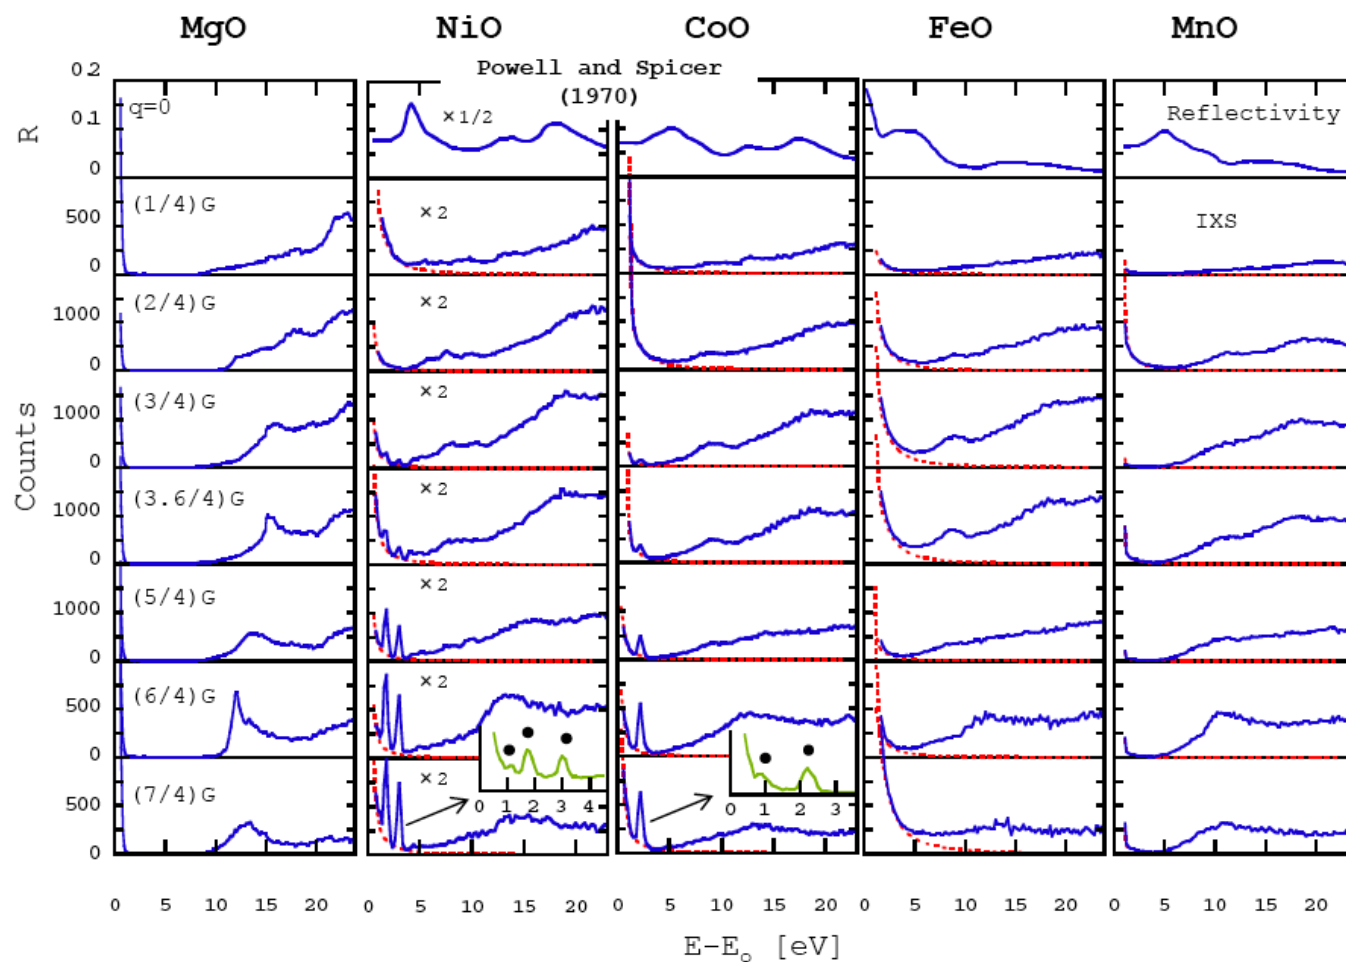

d-d Excitation in NiO  
3 Days/Spectrum

Collective interaction  $\leftrightarrow$  dispersion

Relevance to correlated materials...

Gaps (Mott, Charge Transfer, SC) and  
Mid-IR band in high  $T_c$ s  
f-electron transitions, etc

## Larger Energy Range

Hiraoka et al

# “Momentum Resolved Optical Spectroscopy”

## Conventional Optical Spectroscopy:

(Absorption, Reflectivity)

Information on electronic energy levels but *without* information on inter-atomic correlations or atomic structure

With x-rays, the short wavelength allows direct probe at atomic scale:

*Is an excitation collective or local (does it disperse)?*

*What is the atomic symmetry of an excitation?*

*How does it interact with the surrounding environment?*

Resonant experiment vs non-resonant IXS experiment.

**Non-resonant experiment is simpler and can have higher resolution  
... but badly flux limited**

# The Orbiton Story

(One, mostly experimental, viewpoint)

Orbital order exists  $\rightarrow$  there should be an equivalent excitation

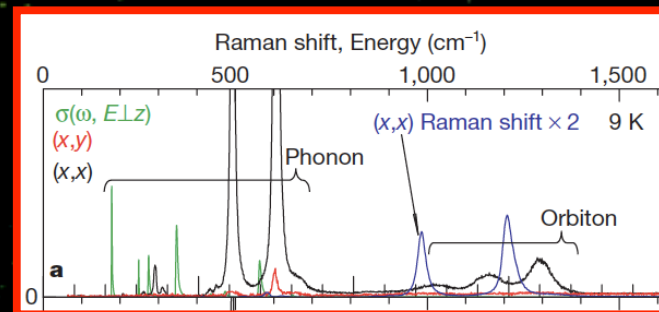

Essential picture is of a correlated d-d excitation - change in electronic wave function on one atom is correlated with change at other atoms.

# X-Ray Raman Scattering

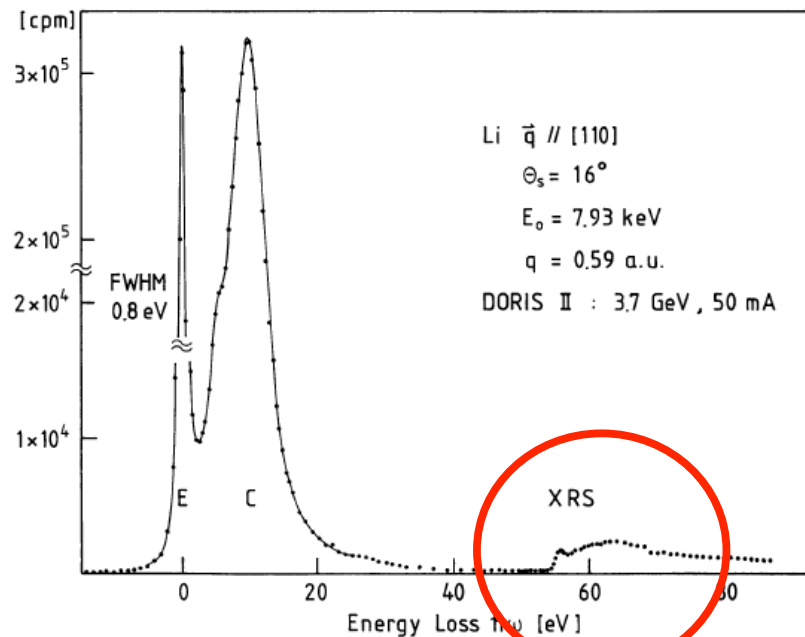

Fig. 1. Raw experimental data for Li single crystal obtained in the dispersion compensating case. The X-ray Raman spectrum (XRS) has an edge like onset at the binding energy of the Li K-electron of about 55 eV. E and C denote the quasielastically scattered Rayleigh line and the  $S(q, \omega)$  profile from the valence electrons, respectively.

Nagasawa, et al, J. Phys. Soc. Jpn. 58 (1989) pp. 710-717

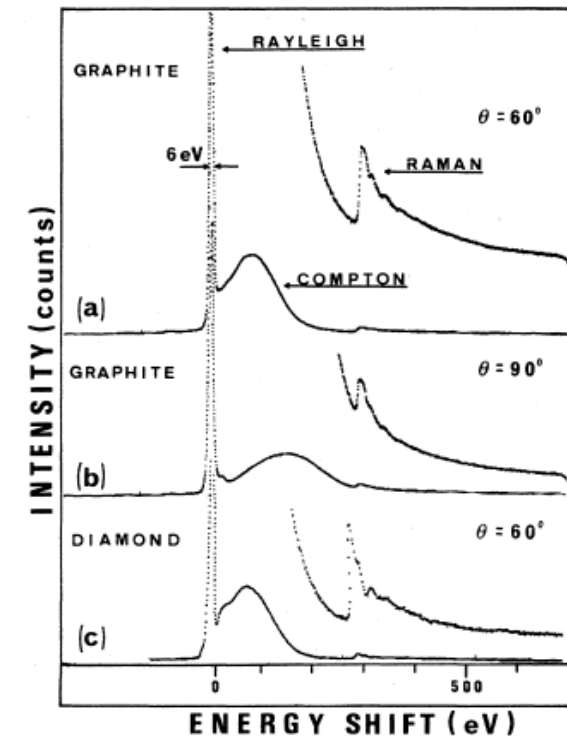

FIG. 2. (a) Inelastic-scattering spectrum from graphite observed at 60°. (b) Inelastic-scattering spectrum from graphite observed at 90°. (c) Inelastic-scattering spectrum from diamond observed at 60°. The Raman parts are inserted with an expanded scale. (a) and (b) were obtained with a Ge(440) dispersing crystal at 8900 eV excitation and (c) was obtained with a Ge(333) crystal at 8400 eV excitation. The Compton shift at 60° scattering does not coincide exactly for graphite and diamond because the excitation energy is slightly different.

Tohji&Udagawa, PRB 39 (1989) 7590

AQRB @ AOFSSR Cheiron School 2013

# X-Ray Raman Scattering

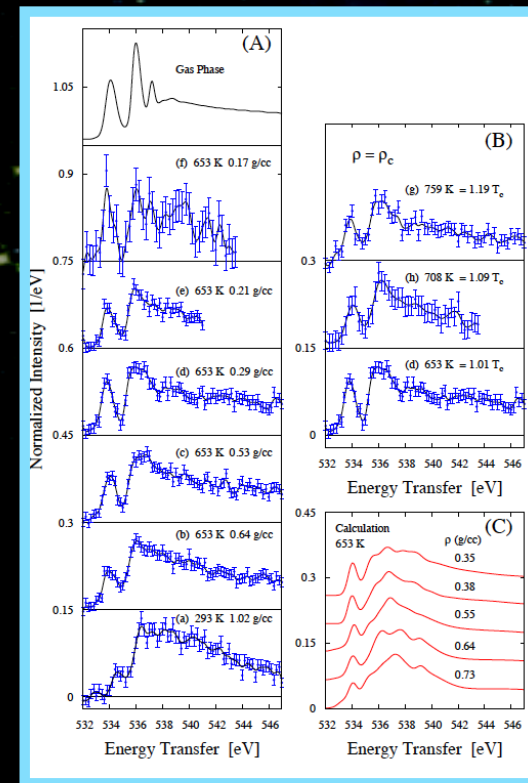

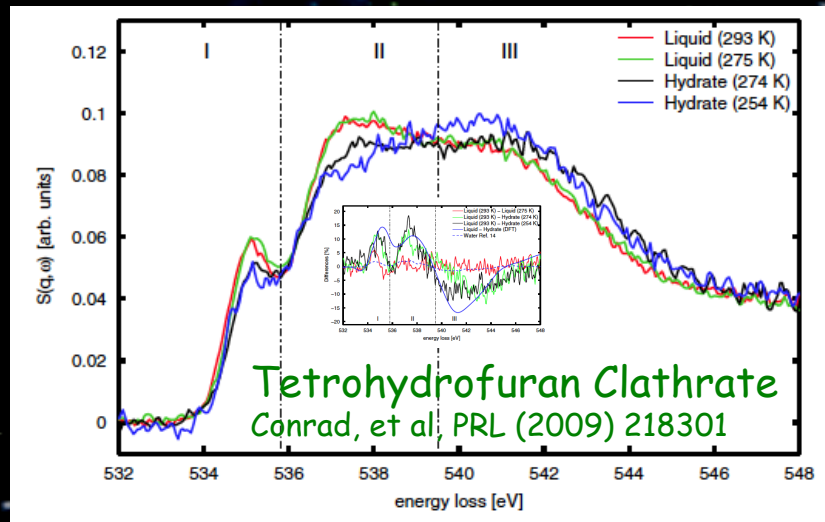

Suppose you would like to measure the structure of the oxygen k-edge (at 532 eV) of a sample inside of complex sample environment...

Diamond:

$$I_{\text{abs}} < 0.5 \text{ } \mu\text{m } 500 \text{ eV}$$

$$I_{\text{abs}} \sim 2 \text{ mm } 10 \text{ keV}$$

Easier at 10 keV than 0.5 keV

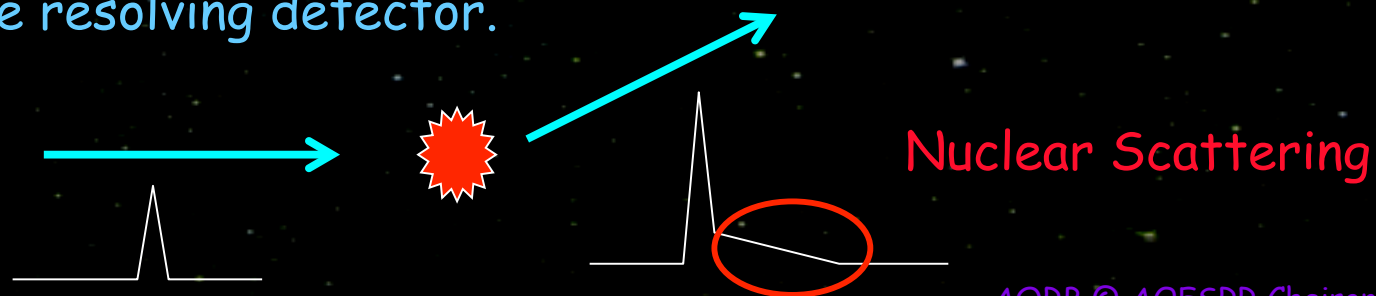

# Nuclear Inelastic Scattering

First Demonstrated (Clearly) by Seto et al 1995

Mössbauer Resonances Exist in Different Nuclei...

Isotope	Transition energy (keV)	Lifetime (ns)	Alpha	Natural abundance (%)
$^{181}\text{Ta}$	6.21	8730	71	100
$^{169}\text{Tm}$	8.41	5.8	220	100
$^{83}\text{Kr}$	9.40	212	20	11.5
$^{57}\text{Fe}$	14.4	141	8.2	2.2
$^{151}\text{Eu}$	21.6	13.7	29	48
$^{149}\text{Sm}$	22.5	10.4	~ 12	14
$^{119}\text{Sn}$	23.9	25.6	~ 5.2	8.6
$^{161}\text{Dy}$	25.6	40	~ 2.5	19

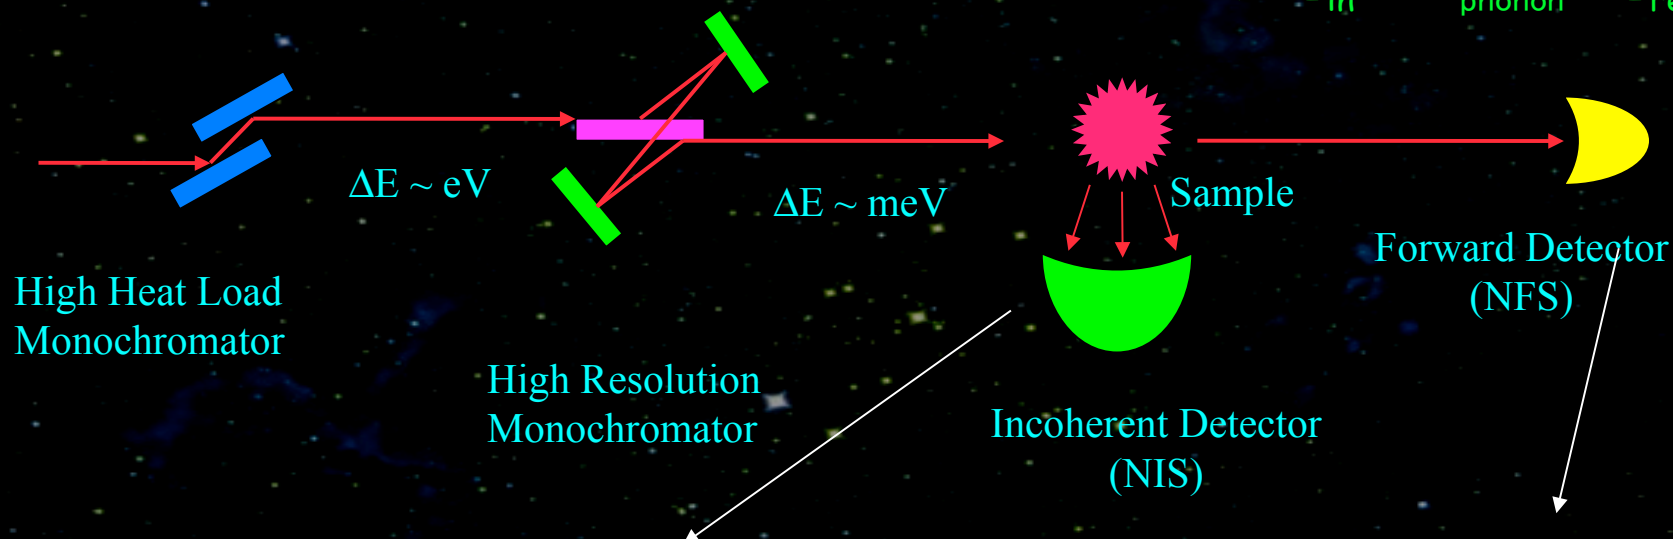

Resonances have relatively long lifetimes so that if one has a pulsed source, one can separate the nuclear scattering by using a fast time resolving detector.

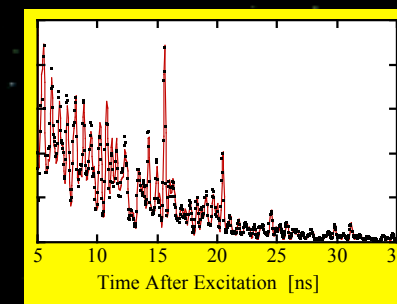

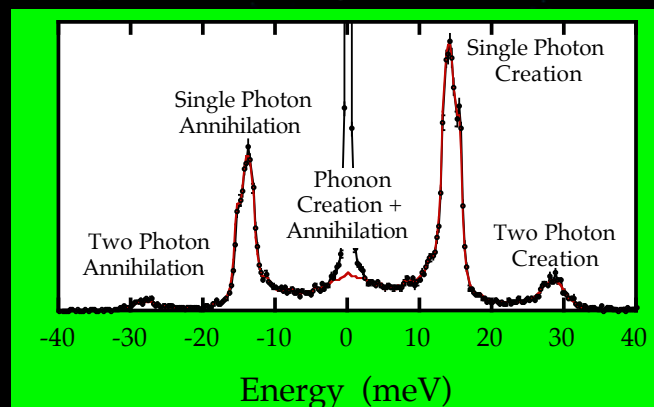

# NIS Setup

Use a narrow bandwidth monochromator  
The nuclear resonance becomes the analyzer.

1.  $E_{in} = E_{res}$
2.  $E_{in} + E_{phonon} = E_{res}$
3.  $E_{in} - E_{phonon} = E_{res}$

Element- Specific  
Projected  
Phonon DOS

Time Domain  
Mossbauer Spectroscopy

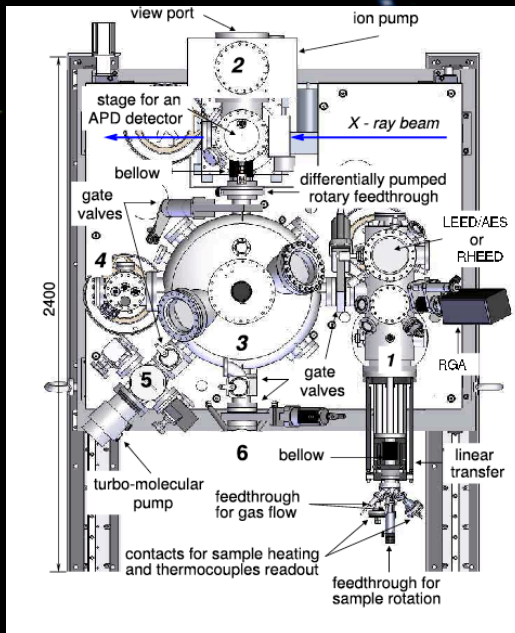

# NIS: Good and Bad

Important things to note:

1. Element and isotope selective.
2. Gives Projected Density of states NOT Dispersion  
(But it does this nearly perfectly)
3. Resolution given only by monochromator  
(analyzer is  $\sim \text{ueV}$ )  
Easier optics but setup not optimized  
(compensated by large cross section)

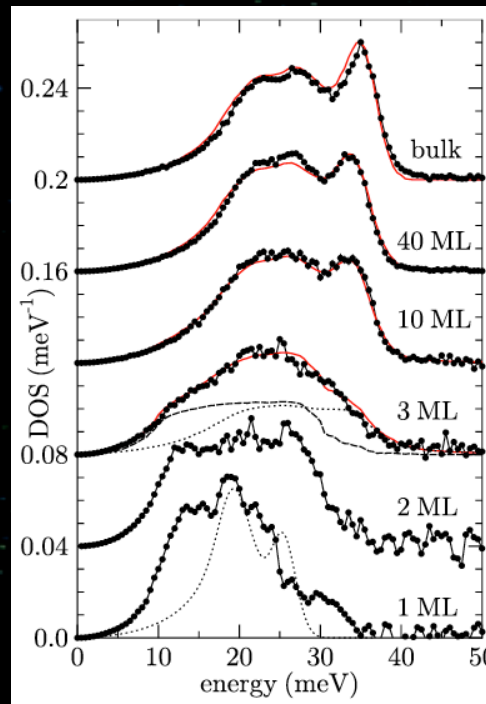

# Surfaces by NIS

The large nuclear cross section allows sensitivity even to monolayers with relatively low backgrounds

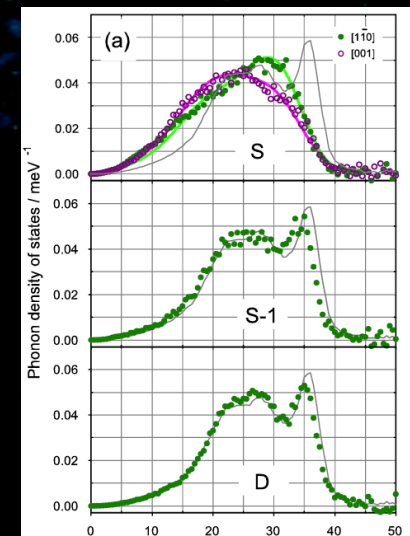

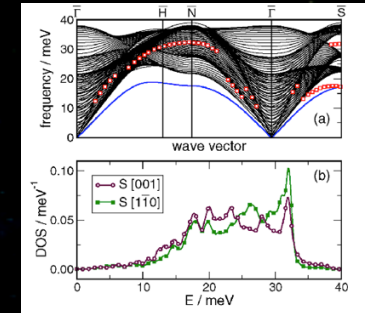

In-Situ Deposition

# Example (NRVS/NIS/NRIXS) In Biology

S. Cramer, et al, JACS

Measurement to determine the products of biological reactions via *site-selective* vibrational spectroscopy and comparison against calcs and model compound.

## A compound in the nitrogen cycle...

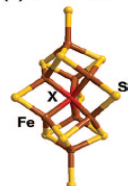

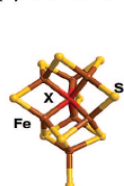

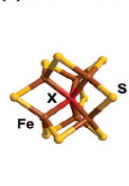

Is X present? How many irons?

(a) 6Fe model

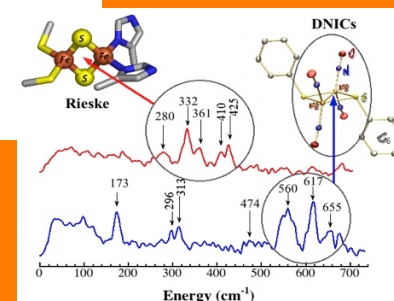

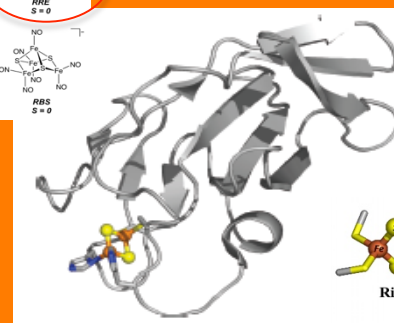

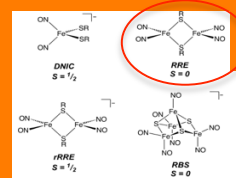

(b) 7Fe model

(c) 8Fe model

## Toxicity of Nitric Oxide (NO)

-> Reaction products previously believed to be mononuclear are dinuclear

# Compton Scattering

For very large  $Q$  and  $\Delta E \ll E$  one can take

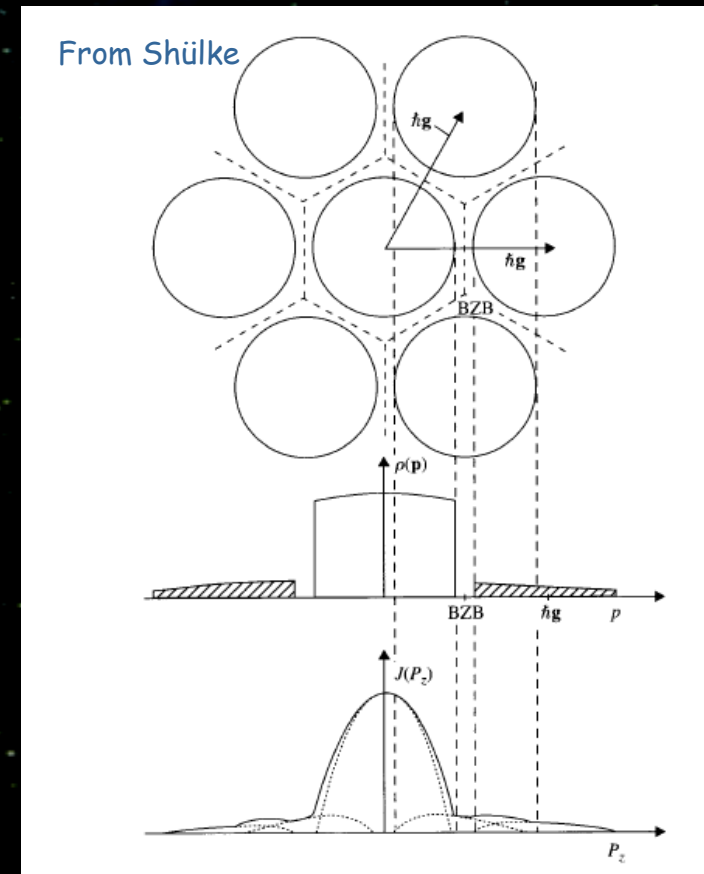

$$S(\mathbf{Q}, \omega) = \frac{m}{\hbar Q} \iint dp_x dp_y \rho(p_z = p_Q)$$

$$\equiv \frac{m}{\hbar Q} J(p_Q)$$

Typical:  $Q \sim 100 \text{ \AA}^{-1}$   
 $E > 100 \text{ keV}$

I.e: Compton scattering projects out the electron momentum density.

Typical of incoherent scattering...

# Three-Dimensional Momentum Density Reconstruction

Three-dimensional momentum density,  $n(\mathbf{p})$ , can be reconstructed from  $\sim 10$  Compton profiles.

$$J(p_z) = \iint n(\mathbf{p}) dp_x dp_y$$

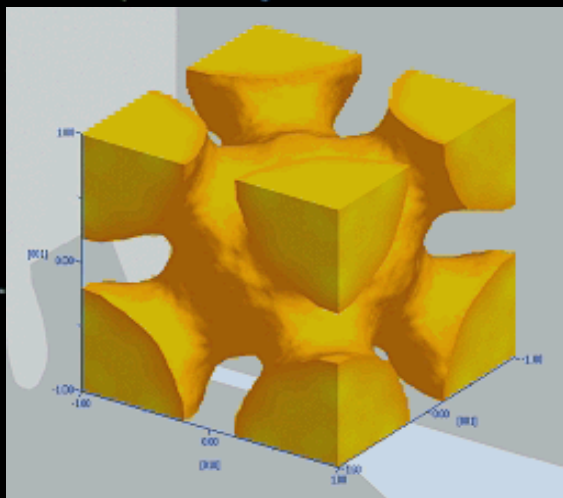

Reconstruction:

- Direct Fourier Method
- Fourier-Bessel Method
- Cormack Method
- Maximum Entropy Method

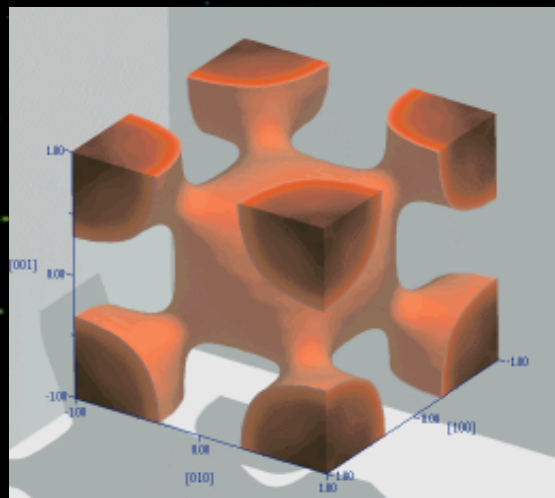

Momentum density,  $n(\mathbf{p})$

Note: a bulk probe that is tolerant of sample imperfections.

# A Nano-Volt Spectrometer

## Rayleigh Scattering of Synchrotron Mossbauer Radiation (RSSMR)

Masuda, Mitsui, Seto, et al, JJAP (2008, 2009)

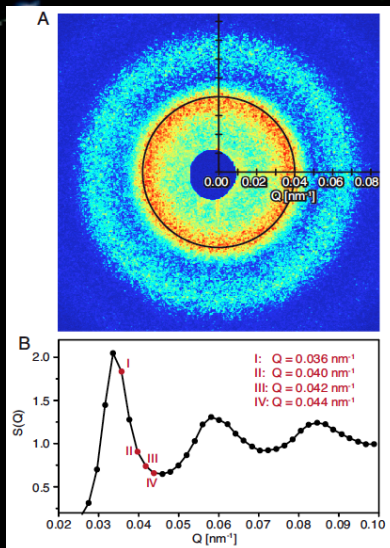

# Beyond Plane Waves

Usual Measurement is a two-point correlation function:

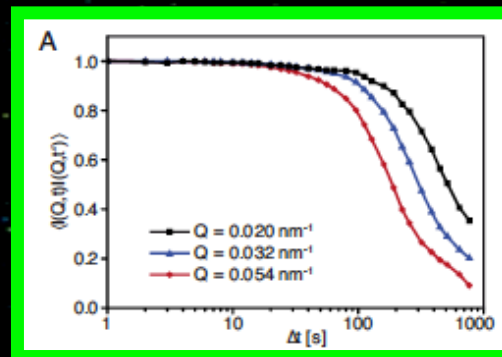

$$S(\mathbf{Q}, \omega) = \frac{1}{2\pi\hbar} \int dt e^{-i\omega t} \int d\mathbf{r} \int d\mathbf{r}' x e^{i\mathbf{Q} \cdot (\mathbf{r} - \mathbf{r}')} \langle \rho(\mathbf{r}', t) \rho(\mathbf{r}, t=0) \rangle$$

Complete picture includes higher order correlation functions

$$I(\mathbf{Q}, t) I(\mathbf{Q}', t') \propto \langle \rho(\mathbf{r}', t) \rho(\mathbf{r}, 0) \rho(\mathbf{s}', t') \rho(\mathbf{s}, 0) \rangle$$

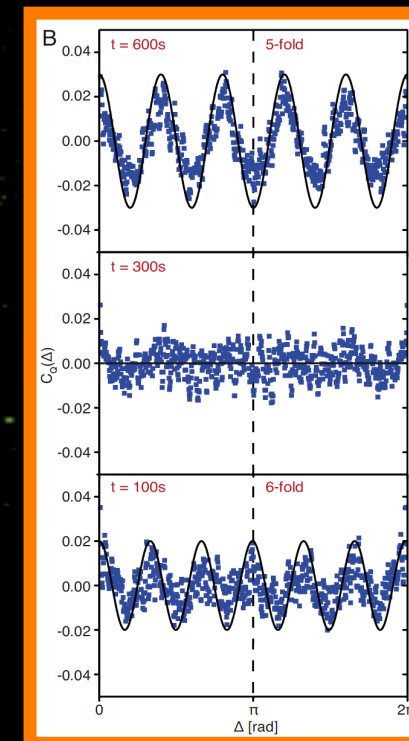

Wochner et al, PNAS (2009)

(A) Autocorrelation at One Q

(B) Cross-Correlation, Different Q

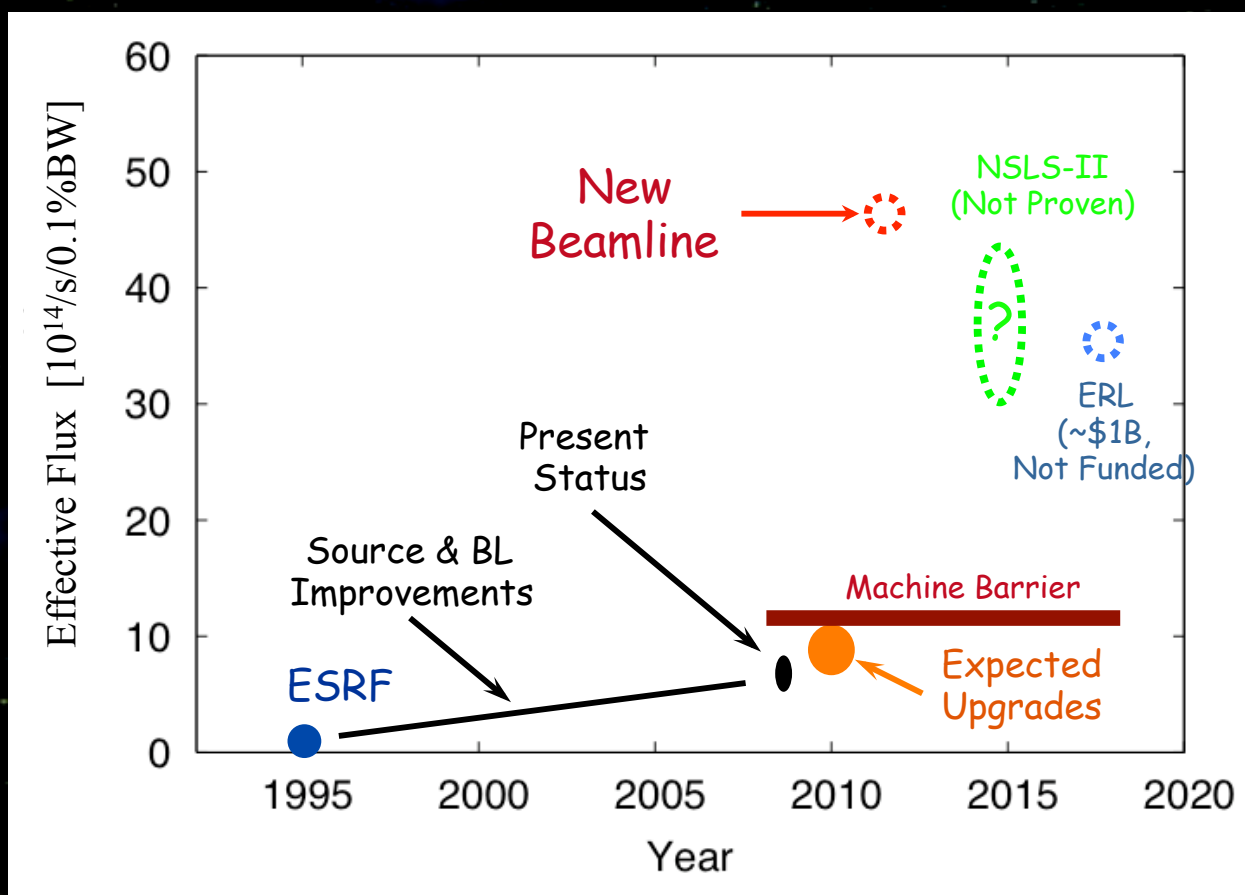

$$C_Q(\Delta) = \frac{\langle I(\mathbf{Q}, \varphi) I(\mathbf{Q}, \varphi + \Delta) \rangle_\varphi - \langle I(\mathbf{Q}, \varphi) \rangle_\varphi^2}{\langle I(\mathbf{Q}, \varphi) \rangle_\varphi^2}$$
